This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

**Usage guidelines**

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

**About Google Book Search**

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

## NAME INDEX.

Abbe (Prof. Cleveland) [death], 174; [obituary article], 332
Abbot (Dr. C. G.), awarded the Rumford Medals, 313
Abbott (G.), Forms of Weathering in Magnesian Limestone, 447
Abbott (W. J. L.), Distribution of Marine and Fresh-water Deposits of Pliocene Age, 356
Adams (Prof. W. S.), awarded the Gold Medal of the Royal Astronomical Society, 393, 475
Alexander (P. F.), The Earliest Voyages Round the World, 1519–1617, 388
Algar (J.), Unsaturated Ketones derived from Diacetoorcinol, 323
Allan (J. A.), Geology of Field Map-area, B.C. and Alberta, 398
Allbutt (Sir Clifford), Science in the School, 241, 462
Allen (Dr. E. J.), Preserving Sprats in Oil, 137
Allen (Dr. H. S.), and H. Moore, A Text-Book of Practical Physics, 106
Amar (J.), The Technique of the Sense Education of Men without Limbs or Sight, 163; Sense Education and Prothesis Apparatus, 204
Amos (A.), Clover Sickness, 263; Ensilage, 301
Amundsen (Capt.), Plans for New Expedition to the North Pole, 452
Anderson (J.), The Nicolson Observatory Beehive and how to Use it, 235
Anderson (Dr. J.) [obituary], 113
Anderson (J.), and Dr. J. Rennie, *Nosema apis* and Isle of Wight Disease, 439
Anderson (J. Wemyss), given the title of Associate Professor by the University of Liverpool, 503
Andrews (E. C.), The Copper Lodes of the Canbelego District, 399
Andrews (E. S.), Elementary Strength of Materials, 365
Angel (A.) [obituary], 413
Angell (John) [obituary article], 56
Angot (Dr. C. A.), elected a Foreign Member of the Royal Swedish Academy of Science, 355
Annandale (Dr. N.), Zoological Results of a Tour in the Far East, 44, 403
Archbold (J. D.), Bequest to Syracuse University, 482
Arctowski (H.), Fluctuations of the Solar Constant, 324
Ariès (E.), The Temperature Function in the Clausius Equation of State, 423
Aries (M.), elected a Correspondant of the Paris Academy of Sciences, 242
Armellini (G.), A Criticism of Fessenkoff's Theory of the Zodiacal Light, 416
Armsby, Fries, and Braman, Energy Values of Red Clover Hay and Maize Meal for Cattle, 376
Armstrong (Dr. E. F.), The Booky Man of Science, 217
Armstrong (Prof. H. E.), and the Work of the Chemical Department of the City and Guilds Engineering College, 195
Armstrong-Jones (Dr. R.), presentation to, 63
Arnoux (A.), Mechanical Protection and Preservation of Eggs, 344
Artis (B.), and H. L. Maxwell, Barium in the Leaves of Tobaccos and Trees, 21
Asayama (C.), Feeding Experiments with Rats, 300
Ascroft (Sir W.) [obituary], 96
Ashworth (Dr. J. H.), Zoology at the British Association, 157
Assheton (Dr. R.), Growth in Length: Embryological Essays, 307
Atkins (Dr. W. R. G.), Some Recent Researches in Plant Physiology, 485
Attwood (W. W.), Glacial Boulder-clay in South-Western Colorado, 117
Aurousseau (M.), West Australian Gneissic and Granitic Rocks, 24

Baber (Z.), The Slaughter of Whales, 114
Backlund (Dr. J. O.) [obituary article], 192
Bacon's War Maps. Europe, embracing all the Countries Involved, 108
Bacot (A.), Hatching and Development of the Larva of the Yellow-fever Mosquito, 383
Baden-Powell (Sir R.), Drawing for Junior Boy Scouts, 402
Bailey (Prof. S. I.), Cluster Variables, 455
Baker (H. A.), The Palæozoic Platform beneath the London Basin, etc., 442
Baker (J. L.), and others, Meldola Memorial, 429
Baker (M. A.), Decennial Index of the *Analyst*, vols. xxxi.–xl., 468
Baker (R. H.), and E. E. Cummings, The Eclipsing Binary RX Herculis, 216; Extra-focal Photometry, 379
Baldwins, Ltd., Gift to the Swansea Technical College, 240
Ball (Dr. J.), The Geography and Geology of West-Central Sinai, 352
Ball (L. C.), Oil Shales in the Port Curtis District, 399
de Ballore (de Montessus), Scales of Seismic Intensity, 478
Banta (A. M.), Sex Intergrades in a Species of Crustacea, 243
Barber (Dr. C. A.), Work of the Coimbatore Cane-breeding Station, 135
Barber (Prof. F. D.), M. L. Fuller, Prof. J. L. Pricer, and Prof. H. W. Adams, First Course in General Science, 348
Bariola (R.), Neolithic Implements found near Cagliari, 453
Barker (Dr. S. G.), Application of the Kerr Effect, 222
Barling (Lt.-Col. G.), appointed Consulting Surgeon to the British Forces in France, 202
Barlow (Sir T.), to deliver the Harveian Oration, 112; the Harveian Lecture, 174
Barnard (Prof.), A Faint Star with Large Proper Motion, 22; awarded the Bruce Gold Medal of the Astronomical Society of the Pacific, 393; and Mr. Adams, Barnard's High Proper-Motion Star, 196
Barnes (A. A.), Hydraulic Flow Reviewed, 87
Barratt (Capt. J. O. Wakelin), A Lunar Rainbow at Etaples, 174
Barrell (J.), Dominantly Fluviatile Origin under Seasonal Rainfall of the Old Red Sandstone, 83; Influence of Silurian-Devonian Climates on the Rise of Air-breathing Vertebrates, 83

Digitized by Google

Bartrum (C. O.), A Clock of Precision, 483
Barus (C.), Interferometer Methods based on the Cleavage of a Diffracted Ray, 83; Non-reversed Spectra of Restricted Coincidence, 402; Path Differences within which Spectrum Interferences are Observable, 402
Barzizza (G. B.), Gnomonica, 326
Bather (Dr. F. A.), on Drawing, 402; The Value of Drawing to the Scientific Worker, 422
Batho (C.), Riveted Joints, 276
Bathurst (Capt. C.), appointed Parliamentary Secretary to the Ministry of Food, 313, 355
Bauer (Dr.), and Mr. Fisk, The Effects of Eclipses on Solar Terrestrial Magnetism, 77
Baur (Prof. E.), Director of the Genetics Institute at Potsdam, 452
Bayliss (Prof. W. M.), Accessory Factors, or "Vitamines," in Diet, 372; Methods of Raising a Low Arterial Pressure, 241; Properties required in Solutions for Intravenous Injection, 179
Bean (Dr. T. H.) [obituary], 393
Beatty (R. T.), The Spectrum of Hydrogen, 169
Beauverie (J.), Influence of Osmotic Pressure on Bacteria, 363
Beddard (Dr. F. E.), Two New Species of Cestodes, 242
Beekly (A. L.), Lenticular Masses of Coal in North Park, Colorado, 117
Beilby (Sir G.), appointed Director of the Board of Fuel Research, 495
Bell (Sir Hugh), Sir Wm. Ramsay, 197
Bell (Dr. W. B.), The Sex Complex, 266
Belogolovy (G. A.), The Development of the Frog Pelobates, 54
Bemmelin (Dr. W. van), Registering Balloon Ascents at Batavia, 21
Benbow (Sir H.) [obituary], 174
Benedicks (C.), A New Effect relative to Thermo-Electricity, etc., 363
Bennett (A. A.), Newton's Method in General Analysis, 243
Benson (A. C.), Literature and Science in Education, 433
Berberich (Dr.), Comet 1916b (Wolf), 437
Bevan (Rev. J. O.), The Towns of Roman Britain, 468
Bierry (H.), Detection of Tubercle Bacilli in Expectorations, etc., 303

# TITLE INDEX.

Aberdeen University, Bequest to: by W. Jackson, 43; by Sir J. Sivewright, 63
Aberystwyth, University College of Wales, Gift to, 321
Aboriginals' Culinary Methods and Kitchen Middens, W. H. D. Le Souef, 53
Absorption Bands, A System of, de Broglie, 183
Acids and Bases in Sea-water, Equilibrium between, L. J. Henderson and E. J. Cohn, 403
Acoustics and Beyond, 306
Actor, The Origin of the, Prof. Ridgeway, 198
Acylsemicarbazides, The Preparation of, J. Bougault, 64
Adelphic Integral in Dynamics, The, Prof. E. T. Whittaker, 323
Admiralty Method of Training Dockyard Apprentices, The, 63
Aerials, Calculation of the Capacity of, Prof. G. W. O. Howe, 158
Aérodonétique. F. W. Lanchester. Translated by Commandant C. Benoît, 465
Aérodynamique. Bases Théoriques de l'Aéronautique, Prof. N. Joukowski, 465
Aeronautical Theories, Prof. G. H. Bryan, 465
Aeroplane: Equations of Motion of an, Prof. E. B. Wilson, 115; Longitudinal Initial Motion, etc., of a Disturbed, Dr. S. Brodetsky, 417; The Case for the Large, F. H. Page, 476
Areoplanes: Dynamical Stability of, J. Hunsaker and others, 465; Mathematical Work on, S. Brodetsky, 97; The Design of, A. W. Judge, 45
Afforestation after the War, Sir J. S. Stirling-Maxwell, 238
Africa: The Flora of all, Dr. W. B. Hemsley, 26; The Flowering Plants of, F. Thonner, 26
African Myxomycetes, Miss A. V. Duthie, 403
Agricultural: Chemistry, Organic (The Chemistry of Plants and Animals), Prof. J. S. Chamberlain, 366; Production, Increased, Prof. W. Somerville, 400
Agriculture: American Books on, 245; and the Wheat Supply, Dr. E. J. Russell, 269; at the British Association, 301; Need of Co-ordination of Science with Practice in, Lord Blyth, 413; Tropical, Risks of, Prof. J. B. Farmer, 299
Agronomy, The Principles of, Prof. F. S. Harris and G. Stewart, 245
*Air*, No. 1, 316
Air: Alveolar Change of Composition of, Dr. H. S. H. Wardlaw, 463; Board, Re-organisation of the, 374; Composition of the, 451; Breathing Vertebrates, Influence of Silurian–Devonian Climates on the Rise of, J. Barrell, 83; Screws: an Introduction to the Aerofoil Theory of Screw Propulsion, M. A. S. Riach, 465
Aircraft Politics in War Time, 498
Alaska: Mineral Resources of, A. H. Brooks, 118; The Kenai Peninsula, G. C. Martin, B. L. Johnson, and U. S. Grant, 118
Alcohol, Effect of Administration of, to the Domestic Fowl, Dr. R. Pearl, 194
*Alcyonium digitatum*, Development of, Miss A. Matthews, 394
Aldehydes with Ketones, Condensation of, iii., H. Ryan and P. Ryan, 323
Algebra: An Arabic, 406; de Abenbéder, Compendio de, J. A. S. Pérez, 406
Algebraic Equations, Roots of, A. Kempner, 396
Alkali, Action of, in the Production of Lipolytically Active Protein, K. G. Falk, 243
Allemands, Les, et la Science, Prof. G. Petit and M. Leudet, 66
Alpine Strain in the Bengali People, Ramaprasad Chanda, 491
Alternating: Currents, A Treatise on the Theory of, Dr. A. Russell, vol. ii., Second edition, 265; in Theory and Practice, W. H. N. James, 265; Electric Currents, Prof. J. A. Fleming, 265
Alto Adige, Handbook and Index to the Names on the Staff Map of the, 176
Aluminium, Determination of, as Oxide, W. Blum, 76
Alvarenga Prize, The, of the College of Physicians of Philadelphia, 355
Amazonian Plants, New, A. Drucke, 454
America: North, Close of Jurassic and Opening of Cretaceous Time in, H. F. Osborn, 119; South, The Timber Resources of, R. Zon, 255; South, Tropical, Proposed Expedition to, Dr. H. Rice, 133; The Oaks of, W. Trelease, 403
American: Association for the Advancement of Science, The, 448; Books on Agriculture, 245; Civil Engineers' Pocket-Book, Edited by M. Merriman, Third edition, 486; Electrical Engineering Firms and Teachers, A. Gray, 361; Geographical Society of New York, Memorial Volume of the Transcontinental Excursion of 1912 of the, 226; Indian, Museum of the, 436; Mammals, The Larger, E. W. Nelson, 304; Museum of Natural History, Attendance at the, 153; Museum of Natural History, Bequest to the, by J. Gaunt, 355; Museum of Natural History, Papers on Fossil Vertebrata, 257; Nature-Study, 2; Permo-Carboniferous Tetrapoda, Prof. S. W. Williston, 356
Ammonia: Sulphate of, Application of, to the Wheat Crop, 97; The Thermodynamic Properties of, F. G. Keyes and R. B. Brownlee, 69
Amœbæ, Cultural, from the Intestine of Man, Dr. H. B. Fantham; The Reviewer, 390
Amsterdam Colonial Institute, The, 22
Amycterides, Revision of the, part v., Dr. E. W. Ferguson, 243
*Analyst*, Decennial Index of the, vols. xxxi.–xl., M. A. Baker, 468
Analyst, The Training of an, F. Browne, 478
Anaphylaxy, The Causes of, J. Danysz, 424
*Anatomy, Journal of*, Change of Editor and Management of the 313
Ancient: Earthworks and Fortified Enclosures, Report of Committee on, 496; Fabrics, Value of Design and Colour in, M. D. C. Crawford, 355
Anemometer, The Linear Hot-Wire, Dr. L. V. King, 155
Anima Animans, 125
Animal Parasites of Man, The, Dr. H. B. Fantham, Prof. J. W. W. Stephens, and Prof. F. V. Theobald, 305
Annealing Glass, Prof. C. V. Boys, 150
Anoplura and Mallophaga, Studies on the, B. F. Cummings, 283
Anthropology at the British Association, 198
Anti-anthrax and other Serums, Dr. R. Norris, 296
Antiseptics: The Alternating Use of, C. Richet, 303; The Comparative Action of, on Pus and on Pure Cultures, A. Lumière, 144
*Aphidoletes meridionalis*, Life-history and Habits of, J. J. Davis, 296
Arboreal: Habits and the Evolution of Man, Prof. G. Elliot Smith, 426; Man, Prof. F. Wood Jones, 426
Arboricultural Pathology, 427
Arc of Certain Curves, Limit of Extensibility of an, M. Petrovitch, 443
Archæological Lights, New, on the Origins of Civilisation in Europe, Sir A. Evans, 12

Digitized by Google

Archæology of the Middle Americas, 70
Archæopteryx, London Specimen of, Pectoral and Pelvic Arches in the, Dr. B. Petronievics and Dr. A. Smith Woodward, 283
*Archives médicales belges*, a Forthcoming Periodical, 273
Archotermopsis, Structure and Biology of, Dr. A. D. Imms, 322
Argentina, Sociedad, de Ciencias Naturales, Sir E. Shackleton and W. H. Hudson elected Corresponding Members of the, 152
Argentine Meteorology, W. G. Davis, 337
Arithmetic: A Shilling, J. W. Robertson, 347; Revision Papers in, C. Pendlebury, 347; Rural, A. G. Ruston, 88
Armagh Observatory, J. A. Hardcastle appointed Astronomer to the, 295
Army, The Health of the British, Sir A. Keogh, 495
Arran Pitchstones, The, Dr. A. Scott, 138
Arsenious Acid Glycerine Jelly, Objects Preserved in, F. A. Rowley, 134
Art of the Cave, Dr. W. Wright, 51
Arterial: Arches in a Rabbit, Abnormality in, E. J. Sheehy, 344; Pressure, Low, Methods of Raising a, Prof. W. M. Bayliss, 241; Pressures, Low, and their Treatment, W. T. Porter, 223
Artificial Limbs, Forthcoming Exhibition of, 273
Artillery and Rainfall, "Moriturus," 229
Arts and Crafts, Forthcoming Exhibition of, 27
Ascaris Infection in Hong Kong, Experiments on, 479
*Ascaris lumbricoides*, Life-history of, Capt. F. H. Stewart, 479
Ashanti, Stone Implements from, A. W. Cardinall, 435
Association of Technical Institutions, Forthcoming Meeting of the, 123, 156
Astronomical: Compass, Visible, Rev. Wm. Hall's, 98; Society of the Pacific, Award of the Bruce Gold Medal to Prof. E. E. Barnard, 393; Station of the Island of Notre-Dame, Position and Co-ordinates of the, G. Bigourdan, 323

## ASTRONOMICAL NOTES.

Comets:
Encke's Comet, Prof. Strömgren, 77; Encke's Comet, Dr. Max Wolf, 156; Ephemeris of Comet 1916*b* (Wolf), R. T. Crawford, 257; A New Comet, Rev. J. Metcalf, 277; Mellish Comet, 1915*a*, 358; Comet 1916*b* (Wolf), Dr. Berberich, 437
Instruments:
Proper Motions by the Blink-Microscope, R. T. A. Innes, 56; Rev. Wm. Hall's Visible Astronomical Compass, 98
Meteors:
Fireball of October 3, 116, 136; Two Large Fireballs, 156; Fireball of October 20, W. F. Denning, 176; The Orionid Shower of 1916, 177; The Leonids of 1916, W. F. Denning, 236; The Meteoric Shower from Biela's Comet, 257; Large Meteor on January 4, W. F. Denning, 379
Observatories:
The Van Vleck Observatory, 22; Hyderabad Observatory, 379; Almanac of the Madrid Observatory, 438; United States Naval Observatory, 455; Report of the Cape Observatory for 1915, 499
Planets:
Observations of Minor Planets in France, 41; Photographs of Mars, G. H. Hamilton, 77; Mercury Visible before Sunrise, 116; The Great Red Spot on Jupiter, F. Sargent, 257; The Search for a Transneptunian Planet, A. Borelly, 277; Total Eclipse of the Moon, 336; Mercury an Evening Star, 336; Long-Period Roberts, 77; Spectrum of the Nebula H IV. 39 Argûs, Dr. Max Wolf, 77; The Masses of Visual Binary Stars, R. T. A. Innes, 99; The Distribution of B Stars, Prof. Charlier, 116; The Spectroscopic Binary $\chi$ Aurigæ, R. K. Young, 116; The Variable Star SZ Cygni, F. C. Leonard, 136; Internal Motion in Spiral Nebulæ, A. van Maanen, 156; The Radial Velocity of $\beta$ Ursæ Majoris, 196; Wolf-Rayet Bands in the Nuclei of Nebulæ, G. F. Paddock, 196; Barnard's High Proper-Motion Star, Prof. Barnard and Mr. Adams, 196; The Eclipsing Binary RX Herculis, R. H. Baker and E. E. Cummings, 216; The Solar Apex Determined by Means of Binary Stars, L. Janssen, 236; Spectrum of the Nebula about Rho Ophiuchi, Dr. V. M. Slipher, 236; The Colours of Stars in Globular Clusters, Dr. Shapley, 257; The Variable Nebula N.G.C. 2261, E. P. Hubble, 298; Parallaxes of Two Stars with Common Motion, O. J. Lee, 317; Rotation and Radial Velocity of N.G.C. 4594, F. G. Pease, 358; The Cepheid Variables, Dr. Ludendorff, 397; Peculiar Stellar Spectra, Miss Cannon, 417; Investigations of Star Clusters, Dr. H. Shapley, 438; Cluster Variables, Prof. S. I. Bailey, 455; Parallaxes of Procyon and Altair, Dr. S. A. Mitchell, 479; Densities of Visual Binary Stars, F. Öpik, 479; The Spectra of Cepheid Variables, Dr. Shapley, 498; Daylight Photography of Stars, A. F. and F. A. Lindemann, 499
Sun:
Measurement of Close Solar Lines, Dr. C. E. St. John and Miss Ware, 40; The Psychology of Differential Measurements, H. H. Plaskett, 41; Effect of Haze on Solar Rotation Measures, R. E. De Lury, 99; Anomalous Dispersion in the Sun, J. Evershed and Dr. Royds; Dr. St. John; Dr. A. S. King, 136; Ultra-Violet Radiation from the Sun, Prof. Birkeland, 177; Radial Motion in Sun-spots, J. Evershed, 196; Solar Prominences in 1916, 277; The Total Solar Eclipse of 1916, February 3, Prof. C. D. Perrine, 418; A Great Sun-spot, 478
Miscellaneous:
A New Astronomical Journal (*La Revue Verte*), 116; A Catalogue of Meteorites, Dr. G. P. Merrill, 196; Spectroscopic Resolving Power, C. M. Sparrow, 216; The Minimum Radiation Visually Perceptible, Dr. H. E. Ives, 216; The Zodiacal Light, W. F. Denning, 277; The Longitude of Washington, 298; The Structure of the Red Lithium Line, Dr. A. S. King, 299; Römer's Discovery of the Velocity of Light, Mrs. K. Meyer, 317; The Cookeville Meteorite, G. P. Merrill, 358; Extra-focal Photometry, R. H. Baker and E. E. Cummings, 379; Aurora Borealis, W. F. Denning; A. A. Rambaut, 397; The Lake Okechobee Meteorite, G. P. Merrill, 455

Astronomy, Egyptian, and the Zodiac, J. Offord, 7
Asymptotic Series, The Theory of, Prof. G. N. Watson, 120
Athenæum Club, Sir R. Hadfield, Sir Douglas Haig, and Prof. Gilbert Murray elected Members of the, 474
Atlas Céleste, Petit, G. Bigourdan, 208
At Last! 285
Atmosphere: Optical Deterioration of the, in July and August, 1916, Sir N. Shaw and Dr. Maurer, 90; and Volcanic Eruptions, Prof. A. Riccò, 190; The Deterioration of the, in the Swiss Alps, Dr. Maurer, Sir N. Shaw, 328
Atmospheric Disturbances of October and November, 1916, The, A. Nodon, 443
*Aulina rotiformis*, etc., Dr. S. Smith, 242
$\chi$ Aurigæ, The Spectroscopic Binary, R. K. Young, 116
Aurora: and Magnetic Disturbances of August 27, 1916,

Digitized by Google

Australia: Prof. J. W. Gregory, 446; Science and Industry in, 310
Australian: Carabidæ, New Species of, T. G. Sloane, 283; Coleoptera, New Species of, A. M. Lea, part xii., 363; Fresh-water Phytoplankton, G. I. Playfair, 463; Microlepidoptera, Studies in, Dr. A. J. Turner, 224; Mollusca, Studies of, C. Hedley, part iii., 363; Mosses, New Species of, Dr. V. H. Brotherus, 283; Neuroptera, R. J. Tillyard, 24, 224; Tabanidæ, F. H. Taylor, part ii., 363
Austrian Universities, Students in the, 282
*Avena fatua* × *A. sativa*, var. *Kherson*, Inheritance of certain Glume Characters in, F. M. Surface, 83
*Aviation and Aeronautical Engineering*, 76
Axinellidæ (Porifera), Revision of the Genera, E. F. Hallmann, part ii., 283
Ayrshire Cattle, Sex-Limited Colour in, Prof. E. N. Wentworth, 480

Bacon's War Maps. Europe, Embracing all the Countries Involved, 108
Bacteriological Research in Bombay, 52
Bacteriology, Aids to, C. G. Moor and W. Partridge. Third edition, 89
*Bacterium campestre* in South Africa, Dr. E. M. Doidge, 500
*Bai*, or "Sand-mist," The, Prof. Y. Wada, 256
Bakhuis Roozeboom Medal awarded to Prof. Schreinemakers, 174
Ball-Joint, A New System of Transmission by a, R. Guillery, 263
Balston Expedition to Peru, The, Dr. C. Lapworth, 442
Barium in the Leaves of Tobaccos and Trees, Amounts of, B. Artis and H. L. Maxwell, 21
Barnard's High Proper-Motion Star, Prof. Barnard and Mr. Adams, 196
Barry Glacier, Retreat of the, B. L. Johnson, 256
Battersea Polytechnic: Courses of Instruction at the, 43; Forthcoming Lecture on "The Saving of the Future," by Dr. C. W. Saleeby, 261; Hygiene Department of the, 241
Beans, Edible, containing a Substance giving a Reaction with Ferric Chloride, H. C. Brill, 378
Bear Island, The Coalfield on, 95
Bedford College for Women, W. N. Jones appointed Lecturer and Head of the Department in Botany at, 63
Beet-Sugar Industry in Siberia, The, 21
Behaviour, Ideational, of Monkeys and Apes, R. M. Yerkes, 403; in Man and other Animals, Ideational and Allied Forms of, R. M. Yerkes, 403
Being and Becoming, L. M. Passano, 234
Beit Memorial Fellowships: for Medical Research, Next Election to, 82; for Scientific Research, Forthcoming Election to, 382
Belemnite Animal, Recent Researches on the, G. C. Crick, 322
Belfast Municipal Technical Institute, Prospectus of the, 63
Belly River Cretaceous, A Marsupial from the, Dr. W. D. Matthew, 175
Bengal, Bihar, and Orissa: Director of Fisheries, Appointment of Mr. T. Southwell, 37; Report of the Department of Fisheries of, 496
Bilharzia Commission in Egypt, Work of the, Dr. R. T. Leiper, 157; Specimens illustrating, in the Natural History Museum, 20
Biology, Volume in, L. J. Henderson, 403
Birds: and the Poet, 147; in Museums, Exhibition of, 235; in Studio and on the Hillside, 30; Migratory, U.S. Treaty with Great Britain for the Protection of, 38; of Shakespeare, The, Sir A. Geikie, 147; Wild, Protection of, in America, 275
Birkbeck College Calendar, 63
Birmingham: and Midland Institute, Scientific Society of the, Entertainment for Soldiers, 314; University, Gift to, by Miss H. Caddick, 441; University, Lt.-Col. G. Barling appointed Consulting Surgeon to the British Forces in France; Alderman F. C. Clayton to act as Vice-Chancellor, 202
Bitter Pit Investigation, Prof. D. McAlpine, 137
Bland-Sutton Institute of Pathology, Endowment of the, as a Memorial to F. C. Melhardo, 273
Blister Rust and White Pine Forests, A Conference on the, 355
"Blizzard": Early Use of the Word, Dr. O. Klotz, 129; Origin of the Word, H. Harries, 169
Board of Trade, Combination of the Commercial Intelligence and the Exhibitions Branches of the, under the name of the Commercial Intelligence Department, 112
Bombay Bacteriological Laboratory, Report of the, 1914, Major W. G. Liston, 52
Books, A Larger Place and a New Use for, Prof. J. A. Green, 217
Borax or Searles Lake, The Salines of, H. S. Gale, 118
Borneo, Journey in, Dr. C. Lumholtz, 133
Botany: A Text-book for Senior Students, D. Thoday, 485; at the British Association, 237
Bradford Technical College: Courses in Chemistry and Dyeing in the, 162; Prospectus of the, 82
Bradshaw Lecture, The: to be delivered by Col. C. J. Symonds, 233; Sir J. Bland-Sutton to deliver the, 503
Brazil Wood, 454
Bread, Standard, 230
Breeding Experiments, Scientific, Miss E. R. Saunders, Prof. Bateson, 238
Brewing Practice, Scientific Method in, Dr. H. Brown, 31
Brine, Evaporation of, from Searles Lake, California, W. B. Hicks, 276
Bristol: General Hospital, Bequest to, by Dr. W. B. Roue, 63; Museum and Art Gallery, Report of the, 414
British Association: Agriculture at the, 301; Botany at the, 237; Committee on Science Teaching in Secondary Schools, Resolution of the, 182; The, at Newcastle, 12, 33; Presidential Address, Sir A. Evans, 12; Presidential Address to the Agriculture Section, Dr. E. J. Russell, 259; Anthropology at the, 198; Presidential Address to the Anthropology Section, Dr. R. R. Marett, 179; Presidential Address to the Botany Section, Dr. A. B. Rendle, 217; Presidential Address to the Chemistry Section, Prof. G. G. Henderson, 34; Chemistry at the, 280; Presidential Address to the Economic Science and Statistics Section, Prof. A. W. Kirkaldy, 139; Presidential Address to the Educational Science Section, Rev. W. Temple, 238; Education at the, 217; Engineering at the, 158; Presidential Address to the Engineering Section, G. Stoney, 159; Presidential Address to the Geography Section, E. A. Reeves, 58; Geology at the, 138; Presidential Address to the Mathematical and Physical Science Section, Prof. A. N. Whitehead, 80; Presidential Address to the Geology Section, Prof W. S. Boulton, 100; Presidential Address to the Physiology Section, Prof. A. R. Cushny, 200; Physiology at the, 178; Zoology at the, 157: Presidential Address to the Zoology Section, Prof. E. W. MacBride, 120; Formation of a Committee to Consider the Needs of Geodetic Research, 120; Mathematics and Physics at the, 120; 1917, The Hon. Sir C. Parsons nominated as President, 18
British: Birds, A. Thorburn, vols. ii. and iii., 30; Columbia and Alberta, Geology of Field Map-area, J. A. Allan, 398; Dyestuff Manufacture, Position and Promise of, 190; Empire, Mineral Resources of the, Prof. C. G. Cullis, 361; Some Conditions of the Stability of the, Dr. Dugald Clerk, 255; Facial Form Changing? Is the, Prof. Keith, 198; Forestry, 105; Gas Industries, Society of, Sir R. Hadfield elected President of the, 495; Honduras, A Chipped Flint Implement found in, St. G. Gray, 154; Industries, Federation of, Formation of a, 74; Federation of, Recommendations of the, 375; Industry and the War, 236; Museum, Annual Report of the, 114; A Portion of a Hippurite Presented to the, by J. A. Plommer, 112; (Natural History), Catalogue of the Ungulate Mammals in the, vol. v., R. Lydekker, 107; Economic Pamphlets, 40; Oil-shale Resources, The Development of, 494; Phytopathology, Ramsbottom, 237; Prisoners of War Book Scheme, The, 82, 241, 362; Rainfall, 1915, Dr. H. R. Mill and C. Salter, 168; Red Cross Society, Sir R. Hudson on Gifts to the, 113; Science Guild, *Journal* of the, November, 342; Trade Bank, Suggested Establishment of a, 74

Ceramic Engineering Building, University of Illinois, Dedication of the, 402
Chemical: Enterprises, Impending Developments in, "Krypton," 489; Industry and Research, The Need of Organisation of, Prof. J. A. Wilkinson, 41; Society, Forthcoming Lectures by Col. C. T. Heycock, Dr. H. T. Brown, and A. C. Chapman, 134; Forthcoming Lectures to the, 495; Proposed New Officers of the, 495; Water Purification, D. B. Byles, 105; World, Need of Well-educated Young Men in the, Dr. M. O. Forster, 143
Chemicals for Laboratory Use, Preparation of, Rintoul, 280
Chemistry: A Class-book of, G. C. Donington, part iv., Metals, 67; and its Relation to National Affairs, Sir W. A. Tilden, 282; at the British Association, 280; Colloid-, A Handbook of, Dr. W. Ostwald. Translated by Prof. M. H. Fischer, 47; Experimental, A Senior, Drs. A. E. Dunstan and F. B. Thole, 67; General, 67; Institute of, Proposed New Regulations of the, 342; of Foul Mud Deposits, Prof. E. A. Letts, 344; of Igneous Magmas and of Organic Metabolism, Apparent Correspondence between the, H. S. Washington, 403; of the Radio-elements, Prof. F. Soddy, French Translation of, 115; Organic, for Agricultural Students, 366; Physical, A System of, Prof. W. C. McC. Lewis, Prof. F. G. Donnan, 25; Physical, for Schools, Dr. H. H. Fenton, 67; Physiological, 167; Synthetic, and the Renascence of British Chemical Industry, Prof. G. T. Morgan, 316
Cheshire Technological Scholarships, Winners of, and McGill University, 43
Chicago, University of, Gift for a Medical Department, by Mr. Rockefeller, 321
Child Hygiene, An Irish Syllabus of Instruction in, 241
Chimie Physique et d'Electrochimie, Cours de Manipulations de, M. Centnerszwer, 407
China, Geological Work in, Dr. T. G. Halle and others, 173
Chlorination Process, Modified, Dr. J. A. Smythe, 280
Chlorine, Free, A Reagent for, in Drinking Water, G. A. Le Roy, 44
Chloroform, Apparatus for the Administration of, Prof. Waller, 178
Cholera Vaccines, Relative Values of Various Kinds of, Capt. Fox, 415
Christianity *in partibus*, 26
*Chrysopa californica*, Life-history of, V L. Wildermuth, 75
Cinchona Plantations in Bengal, The Government, 79
Circle of Scientific, Technical, and Trade Journalists, Visit of the, to Liverpool and Manchester, 302
Citric Solubility and the Fertilising Value of Basic Slag, 96
City and Guilds (Engineering) College, Work of the Chemical Department of the, 195
City and Guilds of London Institute, Department of Technology of, Report of the, 362
Civil Engineering: Constructional Work, 365; Works on, 486
Civil Engineers, Institution of, Awards of the, 153
Civil Service: Home, Committee on Examinations for the, Dr. W. H. Hadow appointed a Member of the, 382; Science and the, 251
Claybury County Asylum, Presentation by the Staff to Dr. R. Armstrong-Jones, 63
Cleator and Cleator Moor: Past and Present, Rev. Cæsar Caine, 205
Cleistogamic Flowers, A. Manganaro, 478
Climate and Crop Production, T. Wibberley, 301
Clock of Precision, A, C. O. Bartrum, 483
Clover Sickness, A. Amos, 263
Coal: and Fuel Economy, 341; and its Economic Utilisation, Prof. J. S. S. Brame, 500; Botanical Aspects of, Dr. Marie Stopes; Prof. A. C. Seward; Prof. Weiss, 237; Measures Amphibia of North America, The, Dr. R. L.

Fasting, Individual and Sex Differences Resulting from, H. D. Marsh, 334
Fatigue: Industrial, Second Interim Report on an Investigation of, Prof. A. F. S. Kent, 353; The Physiology of, 353
Fauna: Littoral Marine, of the Cape Verde Islands, A. W. Waters, 283; of British India, including Ceylon and Burma. Rhynchota: vol. vi., Homoptera; Appendix, W. L. Distant, 107
Faunal Succession of the Lower Carboniferous Rocks of Westmorland and North Lancashire, Prof. Garwood, 76
Fermentation, Influence of Small Rises of Temperature on, C. Richet and H. Cardot, 423
Ferns, The Sorus of, Morphology of, Prof. F. O. Bower, 442
Fertilisers: and Agricultural Production, 400; and Chemical Products, Effects of the War on, 232; in the United Kingdom, Appointment of a Committee on the Increase of, 393; Potassic, Possible, 252; the late Prof. E. B. Voorhees, Revised edition by Prof. J. H. Voorhees, 446
Field Glasses for Army Use, Countess Roberts, 310
Finger-: Print Patterns, The Permanence of, H. Faulds, 388; Sir W. J. Herschel, 389; Printing, The Origin of, Sir W. J. Herschel, 268
Finsbury Technical College, The Chemical Courses of the, 103
Fireball: of October 3, 116; W. F. Denning, 136; of October 20, The, W. F. Denning, 176
Fireballs, Two Large, 156
Firebricks, The Texture of, Dr. J. W. Mellor, 281
Fire Prevention, A Manual of, and Fire Protection for Hospitals, Dr. O. R. Eichel, 368
Fisheries: Inshore, Prof. W. A. Herdman, 136; Inshore, The Exploitation of, Prof. W. A. Herdman, 317; Inshore, of Northumberland, Prof. A. Meek 136; Investigations and Development, 136
Fishes: Age of, Method of Estimating the, Prof. A. Meek, 75; Palæozoic, Some, D. M. S. Watson and H. Day, 135; The Scales of, Prof. A. Meek, 137
Fisica Descritiva, Elementos de, Dr. F. J. S. Gomes and A. R. Machado, Fifth edition, Revised by A. R. Machado, 147
FitzPatrick Lectures, The, to be Delivered by Dr. W. H. R. Rivers, 174
Fizeau's Experiment, Prof. Zeeman, 298
Fleas as a Menace to Man and Domestic Animals, Rev. J. Waterston, 75
Flies, Destruction of, Means Employed for the, Miss O. C. Lodge, 157
Flight, Stability in: Prof. D'Arcy W. Thompson, 409, 490; Sir H. Maxwell, 490
Florida, The Phosphate Deposits of, G. C. Matson, 118
Flotation: of Ores, 246; Process, The, Compiled and Edited by T. A. Rickard, 246
Flour: Government Control over, W. Jago, 250; Milling of, Regulations as to the, 232; Standards, W. Jago, 390
Flowering Plants of Africa, The, F. Thonner, 26
Flowers, Wild, of the North American Mountains, J. W. Henshaw, 2
Fluviatile Origin, Dominantly, under Seasonal Rainfall of the Old Red Sandstone, J. Barrell, 83
Flying Machines, Calculations for, 45
Folk: Memory in Staffordshire, Survivals of, S. A. H. Burne, 214; Psychology, Elements of, Prof. W. Wundt, Translated by Prof. E. L. Schaub, 346
Folk-tales, Personal Experience as an Element in, Miss Freire-Marreco, 199
Food: and Work, 290; Consumption, Need of Curtailment of, Lord Devonport, 451; Economics, Prof. G. Lusk, 173; Increased Production of, Appointment of a Committee on, 435; Increasing the Production of, 333; Ministry of, Information and Statistical Bureau of the, U. Yule appointed Head of the, 393; Production, Sir A. Lee appointed Director-General of, 495; Standards and Man Power, Prof. A. D. Waller, 179; Supplies, Government Control of, 229; Supply of the United Kingdom, Report on the, 451; The Nation's, 471
Foods, Growth Factors of, 300
Foraminifera: Collected off the West of Scotland, Heron-Allen and Earland, 155; Sessile Forms of, Prof. S. J. Hickson, 383
Forest: Economy, S. H. Collins, 302; Insects, Some, in Aberdeenshire, W. Ritchie, 376; Pathology in Forest Regulation, E. P. Meinecke, 176; Service Investigations, E. R. Burdon, 450
Forestry, British: Its Present Position and Outlook after the War, E. P. Stebbing, 105; Past and Future of, Prof. Somerville, 302
Form and Function: a Contribution to the History of Animal Morphology, E. S. Russell, 306
Forrest," "James, Lecture, The, to be Delivered by Sir J. P. Griffith, 132
Forthcoming Books of Science, 60, 115, 155, 156, 196, 298, 316, 378, 397, 417, 456, 478
Fossil: Human Skulls, Recently Discovered, Prof. G. Elliot Smith, 258; Insects, Some, E. Meyrick, 75; The Mark Stirrup Collection of, H. Bolton, 343; Tsetse-fly, The Third, Prof. T. D. A. Cockerell, 70; Vertebrate Animals, 257
France: Collège de, Chair of Social Providence and Assistance at the, 503; Plea for a National Physical Laboratory for, 294; University and Higher Technical Instruction in, Prof. P. Janet, 151; Le Climat de la, Température, Pression, Vents, G. Bigourdan, 127
Frankfurt Institute for Experimental Therapy, Prof. W. Kolle appointed Director of the, 375
Fraunhofer Lines, Suggested Mutual Repulsion of, C. E. St. John, 83
French: Battle-Front, Large-Scale Map of the, 388; Metallurgy, The Future of, Prof. H. C. H. Carpenter; Dr. L. Guillet, 493; War Chemistry, 498
Frost: Thistle, A, a Beautiful Effect of Freezing, R. T. Gunther, 370; Thistles," J. H. Coste, 470
Fuel: Coal and, Economy, 341; Research, A Board of, Appointed, 495
Funereal Figures in Egypt, Prof. F. Petrie, 414
*Furcraea gigantea*, The Fibre of, M. T. Dawe, 55

Galloway and Carrick, Highways and Byways in, Rev. C. H. Dick, 205
"Galvanoset," The, 215
Gaseous Gangrene, Etiology of, M. Weinberg and P. Séguin, 223
Gases: Stepped Ignition in, Prof. W. M. Thornton, 280; The Dynamical Theory of, Prof. J. H. Jeans, 3
Gauges, Limit, Dr. R. T. Glazebrook, 158
Gearing, High-Speed, Distribution of the Load on the Teeth in, 115
Geikie, Prof. James, The late, Dr. M. I. Newbigin, 5
Genera with Microscleres, Revision of the, E. F. Hallmann, 363
General Science, First Course in, Prof. F. D. Barber, M. L. Fuller, Prof. J. L. Pricer, and Prof. H. W. Adams, 348
Genetic Studies in Plants, 119
Genetics, New Institute of, at Potsdam, Prof. E. Baur, Director, 452
Genotypic Factors, The Mutual Effect of, Dr. T. Tammes, 119
Geographical: Association, Annual Meetings of the, 342; Excursion, An International, 226
Geography: Human, Regions in, Prof. Fleure, 380; Generalisations in, G. G. Chisholm, 454; The Teaching of, H. J. Mackinder, 380
Geological: Formations and Structures, A Method of Representing, Dr. J. W. Evans, 138; Society, Awards of the, 393; Work in Canada and Australasia, 398; Work in the United States, 117
Geologists in the War, Work of, 193
Geology: A Composite American Text-book of, 206; A Text-book of, Profs. L. V. Pirsson and C. Schuchert, 2 parts,

## REVIEWS AND OUR BOOKSHELF.

**Agriculture:**
Goff (the late E. S.), Revised by J. G. Moore and L. R. Jones, The Principles of Plant Culture, Eighth edition, 245
Hanson (S. G.), Commercial Egg-Farming, 5
Harris (Prof. F. S.) and G. Stewart, The Principles of Agronomy, 245
McCall (Prof. A. G.), Field and Laboratory Studies of Soils, 245
Voorhees (the late Prof. E. B.), Revised by Prof. J. H. Voorhees, Fertilizers, 446
Weld (Prof. L. D. H.), The Marketing of Farm Products, 245
Wilson (Prof. J.), A Manual of Mendelism, 3

**Anthropology and Archæology:**
Bevan (Rev. J. O.), The Towns of Roman Britain, 468
Breuil (l'Abbé H.), Dr. H. Obermaier, and Col. W. Verner, La Pileta à Benaojan (Malaga) (Espagne), 51
Chanda (R.), The Indo-Aryan Races, part i., 227
Crile (Prof. G. W.), Man—An Adaptive Mechanism, 288
Dennett (R. E.), My Yoruba Alphabet, 108
Haddon (Dr. A. C.), Wundt's Elements of Folk Psychology, 346
Johnston (Sir H. H.). The Peoples and Languages of Sierra Leone, 1
Joyce (T. A.), Central American and West Indian Archæology, 70
Migeod (F. W. H.), Earliest Man, 189
Osborn (Prof. H. F.), Men of the Old Stone Age, Second edition, 45
Thomas (N. W.), Anthropological Report on Sierra Leone, 3 parts, 1; Specimens of Languages from Sierra Leone, 1
Wright (Dr. W.), The Art of the Cave, 51
Wundt (Prof. W.), Elements of Folk Psychology, Translated by Prof. E. L. Schaub, 346

**Biology:**
Assheton (Dr. R.), Growth in Length: Embryological Essays, 307
Atkins (Dr. W. R. G.), Some Recent Researches in Plant Physiology, 485
Bryan (Prof. W. A.), Natural History of Hawaii, 46
Burroughs (J.), The Breath of Life, 125
Child (Prof. C. M.), Individuality in Organisms, 85; Senescence and Rejuvenescence, 85
Dalziel (Dr. J. M.), A Hausa Botanical Vocabulary, 345
Distant (W. L.), The Fauna of British India, including Ceylon and Burma. Rhynchota: vol. vi. Homoptera: Appendix, 107
Ealand (C. A.), Insect Enemies, 427
Fantham (Dr. H. B.), Prof. J. W. W. Stephens, and Prof. F. V. Theobald, The Animal Parasites of Man, 305
Geikie (Sir A.), The Birds of Shakespeare, 147
Gordon (S.), Hill Birds of Scotland, 30
Hawkes (C.), Hitting the Dark Trail, Starshine through Thirty Years of Night, 2
Hemsley (Dr. W. B.), The Flora of all Africa, 26
Henshaw (J. W.), Wild Flowers of the North American Mountains, 2
Johnston (Sir H. H.), Dalziel's A Hausa Botanical Vocabulary, 345
Krogh (Dr. A.), The Respiratory Exchange of Animals and Man, 326
Lamond (H.), The Sea-Trout, 445
Lydekker (R.), Catalogue of the Ungulate Mammals in the British Museum (Natural History), vol. v., 107
Needham (Prof. J. G.), and J. T. Lloyd, The Life of Inland Waters, 2
Rolfs (P. H.), Subtropical Vegetable-Gardening, 189
Russell (E. S.), Form and Function: a Contribution to the History of Animal Morphology, 306
Stebbing (E. P.), British Forestry: its Present Position and Outlook after the War, 105
Thoday (D.), Botany: a Text-book for Senior Students, 485
Thonner (F.), The Flowering Plants of Africa, 26
Thorburn (A.), British Birds, vols. ii. and iii., 30
Webster (A. D.), Tree Wounds and Diseases, 427
Weiss (Prof. F. E.), Dr. A. D. Imms, and W. Robinson, Plants in Health and Disease, 330
Worsdell (W. C.), The Principles of Plant-Teratology, vol. i., 485

**Chemistry:**
Baker (M. A.), Decennial Index of the *Analyst*, vols. xxxi.–xl., 468
Byles (D. B.), Chemical Water Purification, 105
Chamberlain (Prof. J. S.), Organic Agricultural Chemistry (The Chemistry of Plants and Animals), 366
Donington (G. C.), A Class-book of Chemistry, part iv., Metals, 67
Donnan (Prof. F. G.), A System of Physical Chemistry, 25
Dunstan (Dr. A. E.), and Dr. F. B. Thole, A Senior Experimental Chemistry, 67
Fenton (Dr. H. H.), Physical Chemistry for Schools, 67
Folin (Prof. O.), Preservatives and other Chemicals in Foods, 27
Keyes (F. G.), and R. B. Brownlee, The Thermodynamic Properties of Ammonia, 69
Lewis (Prof. W. C. McC.), A System of Physical Chemistry, 2 vols., 25
Luckiesh (M.), Color and its Applications, 366
Mathews (Prof. A. P.), Physiological Chemistry, 167
Mitchell (C. A.), Vinegar: its Manufacture and Examination, 186

Digitized by Google

Ostwald (Dr. W.), A Handbook of Colloid Chemistry, Translated by Prof. M. H. Fischer, 47.
Stein (M. F.), Water-Purification Plants and their Operation, 105
Thorpe (Sir E.), The Right Hon. Sir Henry Enfield Roscoe, 225

**Engineering:**

Andrews (E. S.), Elementary Strength of Materials, 365
Barnes (A. A.), Hydraulic Flow Reviewed, 87
Blanchard (Prof. A. H.), Elements of Highway Engineering, 4
Cain (Prof. W.), Earth Pressure, Retaining Walls, and Bins, 486
Fleming (Prof. J. A.), Alternating Electric Currents, 265
Grialou (Prof. J.), Cours d'Hydraulique, 267
Hay (Dr. A.), An Introductory Course of Continuous-current Engineering, Second edition, 108
James (W. H. N.), Alternating Currents in Theory and Practice, 265
Judge (A. W.), The Design of Aeroplanes, 45
Kapp (Prof. G.), The Principles of Electrical Engineering and their Application, vol. i., 265
Kingsbury (J. E.), The Telephone and Telephone Exchanges: their Invention and Development, 188
Lyle (Prof. W. T.), Parks and Park Engineering, 486
Mather (Prof. T.), The Growth of Telephony, 188
Merriman (M.), American Civil Engineers' Pocket-Book, Third edition, 486
Morrison (Dr. C. E.), and O. L. Brodie, Masonry Dam Design, including High Masonry Dams, Second edition, 486
Rotigliano (Prof. S.), Costruzioni di Strade e Gallerie, 365
Russell (Dr. A.), A Treatise on the Theory of Alternating Currents, vol. ii., Second edition, 265

**Geography and Travel:**

Alexander (P. F.), The Earliest Voyages Round the World, 1519–1617, 388
American Geographical Society of New York, Memorial Volume of the Transcontinental Excursion of 1912 of the, 226
Bacon's Large-Scale Map of the French Battle-Front, 388; Salonika Battle-Front, 428; War Maps, Europe, Embracing all the Countries Involved, 108
Caine (Rev. Cæsar), Cleator and Cleator Moor: Past and Present, 205
Dick (Rev. C. H.), Highways and Byways in Galloway and Carrick, 205
Douie (Sir J.), The Panjab, North-West Frontier Province, and Kashmir, 148
Gregory (Prof. J. W.), Australia, 446
Knipe (H. R.), Tunbridge Wells and Neighbourhood, 48
Martin (Dr. L.), The Physical Geography of Wisconsin, 488
Moreland (A. M.), Through South Westland, Second edition, 48
Wallis (B. C.), Macmillan's Graphic Geographies, The British Isles, 488

**Geology and Mineralogy:**

Ball (Dr. J.), The Geography and Geology of West-Central Sinai, 352
Bonney (Prof. T. G.), Ball's The Geography and Geology of West-Central Sinai, 352
Hoover (T. J.), Concentrating Ores by Flotation, Third edition, 246
Johnson (Prof. B. H.), and L. G. Huntley, Principles of Oil and Gas Production, 487

**Mathematical and Physical Science:**

Allen (Dr. H. S.), and H. Moore, A Text-book of Practical Physics, 106
Bartizza (G. B.), Gnomonica, 326
Boccardi (Prof. G.), Lezioni di Cosmografia, 326
Carmichael (Prof. R. D.), Diophantine Analysis, 126
Centnerszwer (M.), Cours de Manipulations de Chimie Physique et d'Electrochimie, 407
Chamberlin (Prof. T. C.), The Origin of the Earth, 387
Dunk (J. L.), Hyperacoustics, division i., Simultaneous Tonality, 306
Erwin (M.), The Universe and the Atom, 246
Glenn (Prof. O. E.), A Treatise on the Theory of Invariants, 187
Goldsmith (E. T.), The Mechanical Star-bearing Finder, 348
Gomes (Dr. F. J. S.), and A. R. Machado, Elementos de Fisica Descritiva, Fifth edition, Revised by A. R. Machado, 147
Gray (Dr. F. W.), Centnerszwer's Cours de Manipulations de Chimie Physique et d'Electrochimie, 407
Hadley (H. E.), A Manual of Practical Physics, 127
Hart (I. B.), A Student's Heat, 147
Hudson (H. P.), Ruler and Compasses, 347
Hunsaker (J. C.), and others, Dynamical Stability of Aeroplanes, 465
Jeans (Prof. J. H.), The Dynamical Theory of Gases, Second edition, 3
Jessop (Prof. C. M.), Quartic Surfaces with Singular Points, 367
Joly (Prof. J.), Synchronous Signalling in Navigation, 8
Joukowski (Prof. N.), Bases Théoriques de l'Aéronautique. Aérodynamique, 465
Lanchester (F. W.), Aérodonétique, Translated by Commandant C. Benoît, 465
Leib (Dr. D. B.), Problems in the Calculus, with Formulas and Suggestions, 88
Lémeray (E.-M.), Le Principe de Relativité, 368
Marsh (H. W.), Interpolated Six-Place Tables of the Logarithms of Numbers and the Natural and Logarithmic Trigonometric Functions, 208
Martin, Jr. (Prof. L. A.), Text-book of Mechanics, vol. vi., Thermodynamics, 127
Maunder (E. W.), The Stars as Guides for Night-marching in North Latitude 50°, 67
McGegan (J. E.), Star Identifier and Diagrams for the Graphical Solution of Problems in Nautical Astronomy, 406
Merriman (M.), Mathematical Tables for Class-room Use, 88
Meteorological Observations in the Five Years 1911–1915, Results of, also of Underground Temperatures in the Twelve Years 1898–1910, made at the Radcliffe Observatory, Oxford, vol. li., 247
Military Map, The, Elements of Modern Topography (French School of War), 4
Miller (Prof. G. A.), Historical Introduction to Mathematical Literature, 387; Profs. H. F. Blichfeldt and L. E. Dickson, Theory and Applications of Finite Groups, 225
Orpen (T. H.), The Rain-children: a Fairy-tale in Physics, 327
Pendlebury (C.), Revision Papers in Arithmetic, 347
Pérez (J. A.), Texto árabe, Compendio de Algebra de Abenbéder, 406
Phillips (Prof. H. B.), Analytic Geometry, 88
Pidduck (F. B.), A Treatise on Electricity, 6
Riach (M. A. S.), Air Screws: an Introduction to the Aerofoil Theory of Screw Propulsion, 465
Richardson (Prof. O. W.), The Emission of Electricity

Digitized by Google

Night-marching, and Night Boat-work between Latitude 40° N. and 60° N., 67
Woodhouse (G. F.), An Intermediate Text-book of Magnetism and Electricity, 127
Zoretti (Prof. L.), Exercices Numériques et Graphiques de Mathématiques, 347

**Medical Science:**
Bell (Dr. W. B.), The Sex Complex, 266
da Costa (B. F. Bruto), and others, Sleeping Sickness; A Record of Four Years' War against it in the Island of Principe, Translated by Lt.-Col. J. A. Wyllie, 311
Davidson (Sir J. Mackenzie), Localization by X-rays and Stereoscopy, 207
Gaskell (Dr. W. H.), The Involuntary Nervous System, 248
Guest (L. H.), The Nation of the Future, 407
Herms (W. B.), Medical and Veterinary Entomology, 386
Hewlett (Prof. R. T.), Laboratory Manual in General Microbiology, 308; Serum Reactions and Bacterial Therapy, 88
Jones (Prof. F. Wood), Arboreal Man, 426
Kelynack (Dr. T. N.), The Drink Problem of To-day in its Medico-Sociological Aspects, 247
Laboratory Manual in General Microbiology, 308
Lane-Claypon (Dr. J. E.), Milk and its Hygienic Relations, 467
Moor (C. G.), and W. Partridge, Aids to Bacteriology, Third edition, 89
Shuttleworth (Dr. G. E.), and Dr. W. A. Potts, Mentally Deficient Children: their Treatment and Training, Fourth edition, 227
Smith (Prof. G. Elliot), Arboreal Habits and the Evolution of Man, 426
Thomas (Prof. B. A.), and Dr. R. H. Ivy, Applied Immunology, 88

**Metallurgy:**
Brearley (H.), The Heat Treatment of Tool Steel, Second edition, 308
Harbord (F. W.), Brearley's The Heat Treatment of Tool Steel, Second edition, 308
Scott (G. Shaw), The Journal of the Institute of Metals, vol. xv., 69

**Miscellaneous:**
Barber (Prof. F. D.), M. L. Fuller, Prof. J. L. Pricer, and Prof. H. W. Adams, First Course in General Science, 348
Bigourdan (G.), Le Climat de la France: Température, Pression, Vents, 127; Petit Atlas Céleste, 208
Bosworth (G. F.), Ships, Shipping, and Fishing, 68
Brockington (W. A.), Elements of Military Education, 289
Brown (W. A.), The Portland Cement Industry, 368
Bryant (C. L.), Brockington's Elements of Military Education, 289
Burne (S. A. H.), J. T. Slobbs, and H. V. Thompson, The North Staffordshire Field Club, Jubilee Volume, 1865–1915, 488
Cambridge, The Students' Handbook to the University and Colleges of, Fifteenth edition, 148
Catalogue of Scientific Papers, Fourth series (1884–1900), vol. xv., 287
Clodd (E.), Memories, 267
Dicks (A. J.), Trade and Commerce, 68
Eichel (Dr. O. R.), A Manual of Fire Prevention and Fire Protection for Hospitals, 368
Farrar (F. A.), Factories and Great Industries, 68
Farrington (Dr. O. C.), Meteorites: their Structure, Composition, and Terrestrial Relations, 145
Fleming (Prof. J. A.), The Empire at the Cross-Roads, 185
Gower (H. D.), L. S. Jast, and W. W. Topley, The
D. S. Hanchett, History of Domestic and Foreign Commerce of the United States, 2 vols., 42
Jones (W. H. S.), Scientific Method in Schools, 103
Lehfeldt (Prof. R. A.), Economics in the Light of War, 208
Lodge (Sir Oliver J.), Raymond: or Life and Death, 289
Meldola: Raphael, Reminiscences of his Worth and Work by Those Who Knew Him, etc., Edited by J. Marchant, 125
Mill (Dr. H. R.), and C. Salter, British Rainfall, 1915, 168
Muspratt (Dr. E. K.), My Life and Work, 325
Pennell (J.), Pictures of War Work in England, 385; Pictures of the Wonder of Work, 385
Petit (Prof. G.), and M. Leudet, Les Allemands et la Science, 66
Reconstruction, The Elements of, 372
Ripper (Prof. W.), An Appreciation of Work, 385
Shakespeare's England, 2 vols., 491
Shaw (Sir Napier), The Weather Map: an Introduction to Modern Meteorology, 286
Sieff (M.), Manual of Russian Commercial Correspondence, 90
Thorpe (Sir E.), Muspratt's My Life and Work, 325
West (G.), The Practical Principles of Plain Photomicrography, 47
Whyte (A. G.), The World's Wonder Stories for Boys and Girls, 208

**Philosophy and Psychology:**
Boutroux (E.), The Contingency of the Laws of Nature, Translated by F. Rothwell, 426
Dearborn (Prof. G. V. N.), The Influence of Joy, 90
Giron (E.), A Modern Job, Translated by F. Rothwell, 426
Irvine (A. M.), The Dreams of Orlow, 426
Meredith (C. M.), The Bearings of Modern Psychology on Educational Theory and Practice, 27
Mieli (Dr. A.), Le Scuole Ionica, Pythagorica ed Eleata, 165
Patrick (Prof. G. T.), The Psychology of Relaxation, 128
Saeki (Prof. P. Y.), The Nestorian Monument in China, 26
Thompson (Prof. D'Arcy W.), The School of Pythagoras, 165

**Technology:**
Thompson (A. Beeby), Oil-Field Development and Petroleum Mining, 425

Revolving Fluids, Dynamics of, Lord Rayleigh, 503
Rhinocerotidæ of the Oligocene of France, New Species of, J. Repelin, 424
Rhodesia, Dinosaurs in, S. H. Haughton, 481
Rhododendrons and Lime, 171
Rhone Glacier, Changes in the, Prof. T. G. Bonney, 430
Rhonegletscher, Vermessungen am, 1874–1915, 430
*Rhynia gwynne-vaughani*: Dr. R. Kidston and Prof. W. H. Lang, 138; Prof. W. H. Lang, 183
Rifle-sight, The U.S. Telescopic, 377
River Frontiers in Europe, Prof. L. W. Lyde, 395
Rivers, Report on the Investigation of, 20
Rock-carvings at Leonardsberg, Discovery of, 95
Rocky Mountain Spotted Fever, Wolbach, 39
Roman Britain, The Towns of, Rev. J. O. Bevan, 468
Römer's Discovery of the Velocity of Light, Mrs. K. Meyer, 317
Röntgen Interference Patterns, Radial Lines in, J. S. v. d. Lingen, 84
Roscoe, The Rt. Hon. Sir Henry Enfield, Sir E. Thorpe, 225
Rossland, British Columbia, C. W. Drysdale, 398
Rothamsted: Experiment Station, History and Work of

Digitized by Google

Prof. W. S. Adams, 393, 475; College of Physicians of London, Appointment of Harveian Orator, Bradshaw Lecturer, and Milroy Lecturer, 451; Forthcoming Lectures at the, 503; Drawing Society, A Memorial from the, 321; Dublin Society, The Boyle Medal of the, presented to Prof. H. H. Dixon, 451; Institution Lecture Arrangements, 274; Profs. P. Painlevé and V. Volterra elected Honorary Members of the, 273; Microscopical Society, Election of Officers of the, 452; Naval College, Greenwich, Sir H. Jackson appointed President of the, 273
Royal Society: Anniversary Meeting of the, 277; Awards, 212; Medallists of the, 278–79; Nominations for the Council of the, 212; Catalogue of Scientific Papers, The, 287; of Arts, Howard Lectures of the, 482
Rubber: Pests and Diseases of, J. Mitchell, 299; Plantation, 299; Research Work, 357; Standardisation Methods of Preparation of, W. A. Williams and others, 299; Trade, Need of Organisation in the, E. Stevenson, 299; Trees, Collar-rot of, Sharples, 500
Ruhleben Camp School, Prospectus of Work at the, 182
Ruler and Compasses, H. P. Hudson, 347
Rumford Medals, Dr. C. G. Abbot awarded the, 313
Russia, Future Trade with, 453
Russian: Commercial Correspondence, Manual of, M. Sieff, 90; Gift for the Study of, Capt. H. Samman, 302; Journals of Science, New, 54; Polar Expeditions, Two, Prizes Offered for Information Concerning, 97
RX Herculis, The Eclipsing Binary, R. H. Baker and E. E. Cummings, 216

Sakura-jima Eruption of January, 1914, The, Dr. C. Davison, 57
Salivary Reflex, Human, K. S. Lashley, 314
*Salmo fario lacustris*, Migration for Spawning in, L. Roule, 243
Salonika: Battle Front, Large-scale Map of the, 428; The Climate of, 377
Salt Antagonism in Gelatine, W. O. Fenn, 163
Sands: Refractory, and Associated Materials in Hollows, Prof. W. G. Fearnsides and Dr. P. G. H. Boswell, 139; Used in Glass Manufacture, Geological Characters of, Dr. P. G. H. Boswell, 139
"Sandwich" System of Training, A Modified, Dr. Wertheimer, 183
Sanitation, Sanskrit Laws on, Dr. M. Ganga Nath Jha, 75
*Sarcocystis muris*, The Sexual Evolution of, Dr. H. Crawley, 439
Satellites of Spectrum Lines, Distribution of the, Prof. H. Nagaoka, 262
Satyrium, Hybrid Forms in the Genus, Miss A. V. Duthie, 403
Schaefli Prize, The, awarded to Prof. Gogel, 198
Scholarship, Productive Scientific, T. Roosevelt, 262
Science: A General Course of, for the Secondary School, A. D. Hall, 433; and Classics, Sir A. Keogh, 379; and Education, Dr. R. B. Carter, 220; and Industry, J. Swinburne; Lord Moulton, 202; in Australia, 310; with Special Reference to the Work of the National Physical Laboratory, Dr. R. T. Glazebrook, 339; and Manufactures, Dr. M. E. Sadler, 143; and the Civil Service, 251; and the Savant, 66; and the Universities, Dr. Hadow, 217; for the Rank and File, Prof. R. A. Gregory, 400; from an Easy Chair, Sir Ray Lankester, Cheap edition, 115; in Education, F.R.S., F.B.A., 69, 108; Prof. F. Soddy, 90; J. S. Talbot, 217; Rev. Canon J. M. Wilson; The Writer of the Article, 470; The Place of, Sir H. A. Miers, 143; in Public Schools, 400; Rev. Canon J. M. Wilson, 489; in Secondary Schools, Teaching of, Prof. Nunn, 379; in the School, Sir Clifford Allbutt, 241, 462; Curriculum, Lord Milner, 262; Literature and, in Education, 432; A. C. Benson, 433; Scholarships Committee of the Royal Commission for the 1851 Exhibition, Report of the, 203; Teachers, Association of, Resolutions of the, 442; Teaching in Schools, Rev. J. R. Wynne-Edwards, 380; The Booky Man of, Dr. E. F. Armstrong, 217; The Future of, and What Bars the Way, Prof. F. Soddy, 371; The Part of, in the Education of our Governing Classes, L. A. Legros, 182
*Scientia*, 397
Scientific: and Industrial Research, 10, 49; Committee of the Privy Council for, Members of the, 37; Marquess of Crewe appointed a Member of the, 475; Investigation in School, Parents and, O. H. Latter, 400; Knowledge, The Field of, Dr. D. Robertson, 316; Method in Schools, W. H. S. Jones, 103; Papers, Catalogue of, Fourth Series (1884–1900), vol. xv., 287; Quadruple Entente, A Plea for a, Prof. E. Rignano, 408; Prof. A. Meek, 469; Research for National Defence, Lt.-Col. G. O. Squier, 440; in Relation to Industries, Dr. C. P. Steinmetz, 420; State Aid for, Sir J. J. Thomson and others, 272
Scottish Meteorological Society, Officers and Council of the, 355
Scott's Antarctic Expedition, Exhibition of Kinematograph Films of, 153
Screw Gauges, Hardening of, J. H. Lavender, 378
Sea-anemones, Behaviour of the, G. H. Parker, 83; Locomotion of, G. H. Parker, 83; Level in the Ottawa Valley, Late Pleistocene Oscillations of, W. A. Johnston, 499; Trout, 445
Searchlights, C. T. Whitmell, 269
Seismic Intensity, Scales of, de Montessus de Ballore, 478
Selection-Breeding, Dr. R. Pearl, 480
Selenates, Monoclinic Double, of the Nickel Group, Dr. A. E. H. Tutton, 282
Selenium, Detection of Small Quantities of, J. Meunier, 165
Selous, Capt. F. C., The Work of, A. Chapman, 496
Senescence and Rejuvenescence, Prof. C. M. Child, 85
Sense Education: and Prothesis Apparatus, J. Amar, 204; of Men without Limbs or Sight, J. Amar, 163
Serum Reactions and Bacterial Therapy, Prof. R. T. Hewlett, 88
Sex: Complex, The, Dr. W. B. Bell, 266; Intergrades in a Species of Crustacea, A. M. Banta, 243; -limited Factors in Heredity, 479; Transmission in the Lepidoptera, A Further Probable Case of, J. W. H. Harrison, 248
Shackleton Antarctic Expedition, 475; Rescue of the, 18; Return of Eleven Members of the, 212
Shakespeare: and Precious Stones, Dr. G. F. Kunz, 405; The Birds of, Sir A. Geikie, 147
Shakespeare's England, Sir H. Warren, 491
Sheffield University: Bequests to, by Sir G. Franklin, 482; Calendar, 362; Dr. W. E. S. Turner appointed Lecturer on Glass Technology, G. A. Birkett appointed Lecturer in Russian, A. J. Hobson nominated a Pro-Chancellor, 261; Visit of Journalists to, 124
Shell-fisheries, Further Development of the, Dr. J. Johnstone, 136
Ships, Shipping, and Fishing, G. F. Bosworth, 68
Shrike, Red-backed, Breeding Habits of the, J. H. Owen, 394
Siberia, Arctic, A Summer and Winter among the Natives of, Miss Czaplicka, 199
Siberian and Scythian Work, Bronze Castings of, Sir H. Read, 477
Sierra Leone: Anthropological Report on, N. W. Thomas, 3 parts, 1; Specimens of Languages from, N. W. Thomas, 1; The Peoples and Languages of, Sir H. H. Johnston, 1
Signal, Propagation of a, in a Dispersive Medium, Prof. T. H. Havelock, 120
Signalling without Semaphores, 21
Silicates, Natural, The Constitution of the, F. W. Clarke, 118
Sinai: Peninsula, Survey Work in the, Prof. T. G. Bonney, 352; West-Central, The Geography and Geology of, Dr. J. Ball, 352
Sioux Songs, Miss F. Densmore, 496
Slavery, Abolition of, Medals in Connection with the, T. Sheppard, 19
Sleeping Sickness: B. F. Bruto da Costa, J. F. Sant' Anna, A. C. dos Santos, and M. G. de Araujo Alvares, Translated by Lt.-Col. J. A. Wyllie, 311; The Eradication of, from Principe, 311
Snipe, Carrying of Young by the, W. J. Nash, 255

Digitized by Google

Société Helvétique des Sciences Naturelles, Centenary Volume of the, 53
Sodium: Peroxide, Chemical Action of, upon the Oxides of Carbon, C. Zenghelis and S. Horsch, 203; Peroxide, The Chemical Action of, upon Hydrogen Sulphide, C. Zenghelis and S. Horsch, 223; Salts, Limits of Tolerance of Crop Plants for, Headley, Curtis, and Scofield, 114
Soil: Aeration and Crop Production, A. Howard, 315; Cultivation of the, Steam and other Mechanical Tractors in the, C. B. Fisher, 301; Survey of Wisconsin, The, 177
Soils, Field and Laboratory Studies of, Prof. A. G. McCall, 245
Solanaceæ, Chemical Investigation of some Poisonous Plants in the N.O., Dr. J. M. Petrie, 463
Solar: Apex Determined by Means of Binary Stars, The, L. Janssen, 236; Constant, Fluctuations of the, H. Arctowski, 324; Eclipse, The Total, of 1916, February 3, Prof. C. D. Perrine, 418; Lines, Measurement of Close, Dr. C. E. St. John and Miss Ware, 40; Prominences in 1916, 277
Soldiers, Disabled, Medical Treatment for, 293
Sound: -Areas of Great Explosions, Dr. C. Davison, 438; Audibility of, Influence of Wind on, A. Perot, 83; The Abnormal Propagation of, by the Atmosphere, Dr. C. Davison, 71; The Propagation of the, of the Cannonade at the Front, G. Bigourdan, 163; -Waves, The Abnormal Propagation of, in the Atmosphere, S. Fujiwhara, 71
South Africa: Engineering Science in, Prof. J. Orr, 41; Development of the Industries and Resources of, and the Necessity of Research, Prof. J. A. Wilkinson, 437; Farming Industries of, P. ## THE SIR JOHN CASS TECHNICAL INSTITUTE,

JEWRY STREET, ALDGATE, E.C.

Principal—CHARLES A. KEANE, D.Sc., Ph.D., F.I.C.

CHEMISTRY—
CHARLES A. KEANE, D.Sc., Ph.D., F.I.C.
H. J. S. SAND, D.Sc., Ph.D.
G. F. MORRELL, B.Sc. Ph.D., F.I.C.

PHYSICS—
R. S. WILLOWS, M.A., D.Sc.
F. J. HARLOW, B.Sc., A.R.C.S.
F. W. HILL, B.Sc.

MATHEMATICS—
E. C. SNOW, M.A., D.Sc.
H. G. DIXON, M.A.

EVENING CLASSES IN CHEMISTRY, PHYSICS and MATHEMATICS designed to meet the requirements of those engaged in Chemical and Electrical Industries and in trades associated therewith.

The Institute contains well-equipped laboratories in which every facility is provided for

**Advanced Practical Work and Research**

both in the afternoon and evening.

A full curriculum for the B.Sc. examination of London University in Physics, Chemistry and Mathematics is provided under recognised teachers of the University.

**New Session begins Monday, September 25th.**

For details of the courses apply at the Office of the Institute or by letter to the PRINCIPAL.

## THE SIR JOHN CASS TECHNICAL INSTITUTE,

JEWRY STREET, ALDGATE, E.C.

**EVENING CLASSES IN METALLURGY.**

Head of Department ..... C. O. BANNISTER, A.R.S.M., M.I.M.M., F.I.C.

Lecturer on Metallurgy .. G. PATCHIN, A.R.S.M.

Lecturer on Metal Testing .. E. M. BOOTE.

Elementary, Intermediate, and Advanced Metallurgy forming a graded four years' curriculum. Special Courses on Assaying, Metallography (including Pyrometry), the Metallurgy of Gold and Silver, the Metallurgy of Iron and Steel, Heat Treatment of Metals and Alloys, Mechanical Testing of Metals and Alloys.

The courses are suited to the requirements of those engaged in Metallurgical Industries. Assay Laboratories, and to those intending to take up Metallurgical work in the Colonies.

The Laboratories are open for

**Advanced Practical Work and Research**

both in the afternoon and evening.

**New Session begins Monday, September 25.**

For details of the classes apply at the office of the Institute or by letter to the PRINCIPAL.

*NEW SESSION OPENS MONDAY, SEPTEMBER 25.*

## BIRKBECK COLLEGE,

BREAMS BUILDINGS, CHANCERY LANE, E.C.

**UNIVERSITY OF LONDON.**

**COURSES OF STUDY (DAY AND EVENING)**

FOR DEGREES IN

**ARTS, SCIENCE, ECONOMICS, LAWS,**

Under RECOGNISED TEACHERS of the University.

**ARTS.**—Latin, Greek, English, French, German, Italian, History, Geography, Logic, Economics, Mathematics (Pure and Applied).

**SCIENCE.**—Chemistry, Physics, Mathematics (Pure and Applied), Botany, Zoology, Geology.

***Evening Courses for the Degrees in Economics and Laws***

POST-GRADUATE AND RESEARCH WORK.

SESSIONAL FEES { *Day:* Arts, £10 10s.; Science, £17 10s. *Evening:* Arts, Science, or Economics, £5 5s.

*Competition for 16 Intermediate University Free Studentships commences on September 11.*

**Matriculation Courses and Accountancy.**

*Prospectus post free, Calendar 3d. (by post 5d.), from the Secretary.*

## SOUTH-WESTERN POLYTECHNIC INSTITUTE, CHELSEA.

Day and Evening Courses in the Faculty of Science and Engineering.
Technical Chemical Courses.
Pharmacy and Dispensing Courses.
Particulars may be obtained on application to the Secretary (Room 44). SIDNEY SKINNER, M.A., Principal.

Telephone: Western 899.

THE MANCHESTER MUNICIPAL

## SCHOOL OF TECHNOLOGY

(UNIVERSITY OF MANCHESTER).

PRINCIPAL: J. C. M. GARNETT, M.A. (late Fellow of Trinity College, Cambridge).

The Prospectus, forwarded free on application, gives particulars of the courses leading to the Manchester University degrees in the Faculty of Technology, in the following departments:—

MECHANICAL ENGINEERING,
ELECTRICAL ENGINEERING,
SANITARY ENGINEERING (including Municipal Engineering),
THE CHEMICAL INDUSTRIES (including General Chemical Technology, Bleaching, Dyeing, Printing, Papermaking, Brewing, and Metallurgy),
THE TEXTILE INDUSTRIES,
PRINTING AND PHOTOGRAPHIC TECHNOLOGY,
MINING,
ARCHITECTURE.

During the Session 1916-1917, First Year Courses will be specially adapted to the requirements of students who may wish to take Commissions in H.M. Forces.

**ENGINEERING AND TECHNICAL OPTICS.**

## NORTHAMPTON POLYTECHNIC INSTITUTE,

ST. JOHN STREET, LONDON, E.C.

**ENGINEERING DAY COLLEGE.**

Full Day Courses in the Theory and Practice of Civil, Mechanical, and Electrical Engineering will commence on Monday, October 2, 1916. The Courses in Civil and Mechanical Engineering include specialisation in Automobile and Aeronautical Engineering, and those in Electrical Engineering include specialisation in Radio-Telegraphy.

*Entrance Examination* on Tuesday and Wednesday, September 26 and 27, 1916. These courses include periods spent in commercial workshops, and extend over four years. They also prepare for the Degree of B.Sc. in Engineering at the University of London. Fees £15 or £11 per annum.

*Three Entrance Scholarships* of the value of £52 each will be offered for competition at the Entrance Examination in September, 1916.

**TECHNICAL OPTICS.**

Full and Part Time Courses in all branches of this important department of Applied Science will be given in specially equipped laboratories and lecture rooms. *An Aitchison Scholarship* (value £30) will be offered in this department at the Entrance Examination.

Full particulars as to fees, dates, &c., and all information respecting the work of the Institute, can be obtained at the Institute or on application to

R. MULLINEUX WALMSLEY, D.Sc., Principal.

UNIVERSITY OF LONDON.

## KING'S COLLEGE, AND KING'S COLLEGE FOR WOMEN.

FACULTY OF SCIENCE.

In this Faculty a Course of Study in Science is provided suitable for general education or for the Examinations of the London and other Universities.

Students are admitted either as Regular or Occasional Students. Several valuable Scholarships and Prizes are offered.

The Laboratories of the College are open to post-Graduates and Research Students.

The following are the Departments under the charge of the various Professors, assisted by the Junior Staff:—

The next TERM begins WEDNESDAY, OCTOBER 4, 1916.

For particulars as to this and other Faculties of the College—Engineering, Medicine, Arts, Laws, and Theology—apply to the SECRETARY, King's College, Strand, W.C.

UNIVERSITY OF LONDON.

## KING'S COLLEGE.

EVENING CLASS DEPARTMENT.

COURSES are arranged for the INTERMEDIATE and FINAL EXAMINATIONS for the B.A. and B.Sc. DEGREES of the UNIVERSITY OF LONDON. Students taking the full Course pay Composition Fees and rank as Internal Students of the University.

The Classes are also open to Occasional Students in separate subjects.

NEXT TERM will BEGIN on WEDNESDAY, October 4, 1916.

For full information and Prospectus apply to the DEAN (Mr. R. W. K. Edwards) or to the SECRETARY, King's College, Strand, London, W.C.

## BATTERSEA POLYTECHNIC, LONDON, S.W.

Principal—F. H. NEWMAN, M.A., Ph.D.

Head of Chemical Department—J. WILSON, M.Sc., F.I.C.

Day and Evening Courses for London B.Sc. (Pass and Honours).

Three Years' Day Diploma Course in Applied Chemistry and Chemical Engineering.

Special Evening Courses (Lectures and Laboratory) in Applied Chemistry.

*Coal Tar Colours.*
Tuesday — J. WILSON, M.Sc., F.I.C.

*Chemical Engineering.*
Thursday and Friday—J. W. HINCHLEY, A.R.S.M., Wh.Sc., and J. W. WOOD, M.Sc. (Tech.).

*Fuel and Engineering Materials.*
Wednesday—J. W. WOOD, M.Sc. (Tech.).

*Bacteriology.*
Tuesday, Wednesday, & Friday—J. H. JOHNSTON, M.Sc., F.I.C.

*Analysis of Foods, &c.*
Wednesday—J. H. JOHNSTON, M.Sc., F.I.C.

*Drug Assay and Materia Medica.*
Wednesday and Thursday—R. E. GRIFFITHS, B.Sc., A.I.C.

*Pharmacy and Dispensing*
Wednesday and Thursday—R. E. GRIFFITHS, B.Sc., A.I.C.

*Oils and Fats.*
Monday—J. L. WHITE, D.Sc.

*Lubricating Oils.*
Friday—W. H. SIMMONS, B.Sc.

*Paper Making.*
Monday—SHELDON LEICESTER.

*Paper Testing.*
Friday—SHELDON LEICESTER.

*Dyeing and Cleaning.*
Thursday—FRANKLIN WALKER.

Next Session begins on Monday, September 25.

Abridged Calendar gratis on application to the SECRETARY.

## THE ROYAL TECHNICAL COLLEGE, GLASGOW.

SESSION 1916–17 BEGINS ON SEPTEMBER 26.

The Diploma of the College is granted in the following Departments:—Civil Engineering, Mechanical Engineering, Electrical Engineering, Mining, Naval Architecture, Chemistry, Metallurgy, Building, Textile Manufacture, Dyeing, and Sugar Manufacture. A Course for a Joint Diploma in Architecture has been arranged in conjunction with the Glasgow School of Art.

The Diploma Course extends over either three or four Sessions, and the average fee per Session is £12 12s.

The College is affiliated to the University of Glasgow, and the Degrees of the University in Engineering and Applied Chemistry are open to its students.

Full Courses of Instruction are also provided in the Schools of Navigation, Wireless Telegraphy, and Bakery.

The Calendar (price 1s., by post 1s. 4d.) and Prospectuses (free) will be sent on application to the DIRECTOR.

## UNIVERSITY OF MANCHESTER.

CHEMISTRY COURSES.

Full particulars of the Lecture and Laboratory Courses qualifying for Degrees in Chemistry will be forwarded on application to the REGISTRAR.

Applications for admission to the Research Laboratories should be made to the DIRECTOR OF THE CHEMICAL LABORATORIES.

## CITY OF BRADFORD EDUCATION COMMITTEE.

## TECHNICAL COLLEGE.

Principal—WALTER M. GARDNER, M.Sc., F.I.C.

DIPLOMA COURSE extending over three (in some cases four) years in
TEXTILE MANUFACTURE (Yarns and Cloth).
DYEING.
CHEMISTRY (Analytical and Manufacturing).
ENGINEERING (Civil, Mechanical, and Electrical).

These Courses afford the necessary scientific training for the industries concerned.

The Practical Equipment is exceptionally complete, the sheds and workshops covering an area of about three-quarters of an acre.

Enquiries are welcomed from firms requiring well-trained men.

Prospectuses and further particulars from the PRINCIPAL OF THE COLLEGE, or the DIRECTOR OF EDUCATION, Town Hall, Bradford.

(BY ORDER.)

## EDINBURGH & EAST OF SCOTLAND COLLEGE OF AGRICULTURE.

SESSION 1916–17.

The WINTER SESSION begins on TUESDAY, OCTOBER 10.

The DAY CLASSES, in conjunction with certain University Classes, provide full courses of instruction in Agriculture, Horticulture, and Forestry.

Full particulars of Courses and Classes, and also of Bursaries tenable at the College, are given in the Calendar, copies of which may be obtained on application.

All the College Courses are open to Women Students.

ALEXANDER M'CALLUM, M.A., LL.B.,
Director and Secretary.

13 George Square, Edinburgh.

## BEDFORD COLLEGE FOR WOMEN (UNIVERSITY OF LONDON), REGENT'S PARK, N.W.

SCIENTIFIC INSTRUCTION IN HYGIENE.

MICHAELMAS TERM BEGINS THURSDAY, OCTOBER 5, 1916.

For College Calendar and particulars of Scholarships and Bursaries apply to the PRINCIPAL, Miss M. J. TUKE, M.A.

## THE UNIVERSITY OF SHEFFIELD.

EDGAR ALLEN SCHOLARSHIPS

The following ENTRANCE SCHOLARSHIPS, each of the value of £100 per annum, and tenable for three years, are offered:—

(*a*) TWO SCHOLARSHIPS, open to men and women who will not have completed their 20th year at the beginning of the University Session in which they enter the University.

(*b*) TWO SCHOLARSHIPS, restricted to the "sons of workmen earning daily or weekly wages and foremen of workmen and managers."

An examination for the above Scholarships will be held in December next, and entries must be sent to the REGISTRAR by October 31.

Full particulars of these Scholarships may be obtained free from

W. M. GIBBONS, Registrar.

## THE UNIVERSITY OF SHEFFIELD.

COURSES are held and DEGREES are awarded in the following Faculties: ARTS (including Architecture), PURE SCIENCE, MEDICINE, LAW, APPLIED SCIENCE (including Engineering, Metallurgy, Mining, and Glass Technology).

The SESSION 1916–17 commences OCTOBER 4, 1916.

Entrance and Post-Graduate Scholarships are awarded each year.

Prospectuses, giving full information, may be obtained from

W. M. GIBBONS, Registrar.

## THE UNIVERSITY OF SHEFFIELD.

DEPARTMENT OF GEOGRAPHY.

A TEMPORARY LECTURER is required in the Department of Geography for the Session 1916–17, in the absence of the Lecturer on War Service. Salary £200. The appointment is open to a man, ineligible for war service, or to a woman. Further particulars may be obtained from the undersigned.

W. M. GIBBONS, Registrar.

## SECONDARY SCHOOL (DUAL), CASTLEFORD, YORKS.

WANTED in January, a MISTRESS to teach Science and some Mathematics, Geography desirable. Salary £130 to £170, according to qualification and experience.

The Mistress appointed will be eligible for the post of Senior Mistress now vacant.

Apply Mr. C. T. LIGHTLEY (Clerk to the Governors), 77 Carlton Street, Castleford.

# THE PRINCIPLES OF ELECTRICAL ENGINEERING AND THEIR APPLICATION.

**Vol. I. PRINCIPLES. xii+356 pages.**
**Fully Illustrated. Demy 8vo. 15s. net.**

**Vol. II. APPLICATION. Will be ready shortly.**

## By GISBERT KAPP, M.I.C.E.,

*Professor of Electrical Engineering, University of Birmingham.*

This book is intended as a text-book for all engineering students and as a handbook for the general engineer. The latter is not interested in minute details and refinement of design, but he is interested in the question whether and how any particular piece of electrical plant can be used or adapted for a particular purpose. To answer such a question he must not only have mastered the fundamental principles such as are given in the text-books on magnetism and electricity, but also, in a general way at least, the application of these principles to the construction, testing and working of electrical plant. These matters are treated in the present book, Principles mainly in Vol. I. and Application in Vol. II.

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

"To the solid ground
Of Nature trusts the mind which builds for aye."—WORDSWORTH.

THURSDAY, SEPTEMBER 7, 1916.

## THE PEOPLES AND LANGUAGES OF SIERRA LEONE.

*Anthropological Report on Sierra Leone.* By Northcote W. Thomas. Part i., *Law and Custom of the Timne and other Tribes.* Pp. 196. Part ii., *Timne-English Dictionary.* Pp. viii+139. Part iii., *Timne Grammar and Stories.* Pp. xxx+86.

*Specimens of Languages from Sierra Leone.* By Northcote W. Thomas. Pp. 62. (London: Harrison and Sons, 1916.)

MR. NORTHCOTE THOMAS, employed for a number of years as Government Ethnologist in Southern Nigeria, was transferred recently to the Sierra Leone colony and protectorate to serve there in a like capacity. The first results of his work have now been published by the Crown Agents for the Colonies, and will not disappoint those whose expectations have been already raised over the remarkable research work conducted by Mr. Thomas amongst the tribes of Southern Nigeria—in which direction, be it observed, he revealed much that was new and interesting regarding the Semi-Bantu languages of the Upper Cross River basin.

Sierra Leone is a British possession of some 30,000 square miles in area, but, like the adjoining regions of Liberia and French and Portuguese Guinea, its interest is not measured by the square mile. All this portion of (originally densely forested) West Africa has been the refuge of oppressed tribes driven out of the interior pasture-lands, and also the goal of negroid, cattle-keeping tribes of the mountainous regions of Senegambia, who have been drawn coastwards by the attraction of the sea and its salt, and the commerce brought by European ships, perhaps from the days of the Carthaginians onwards. One feature amongst many others makes this region of Guinea singularly interesting to those who are exploring African ethnology, and that is the presence there of Semi-Bantu languages. We are already much indebted to Mr. Thomas for the information he has placed at our disposal regarding the Semi-Bantu speech forms of the Upper Cross River. The writer of this review, moreover, has received of late invaluable information regarding the Semi-Bantu languages of Eastern Nigeria, first revealed, like so much else in African linguistics, by Koelle's vocabularies. (Mr. Thomas, it should be remarked, both in the works under review and in those alluded to on Southern Nigeria, has always done full justice to Sigismund Koelle, an Anglican missionary of the middle of the nineteenth century, whose "Polyglotta Africana" has only of late received the full appreciation it deserves from students of African languages.) The Semi-Bantu languages are represented at the present day by small and scattered groups in the Bauchi hills and in the Middle Benue basin (Eastern Nigeria), in the Kaduna region of Central Nigeria, in a small portion of Togoland, in Sierra Leone and in Portuguese Guinea, and near the Upper Gambia, and, so far as we are aware, nowhere else. The affinities between each of these groups is indubitable when a comparative study is made, as also their inherent affinity with Bantu speech both in syntax and word-roots.

Two groups of these Semi-Bantu languages are confined in their area (more or less) to the Sierra Leone colony and protectorate: Bulom, originally the dominant speech of the Sierra Leone coast line, and Temne (Timne). The Temne people and language are distributed over the western part of Sierra Leone, with extensions (speaking different dialects) into French Guinea. At the present day the Bulom language is said to be nearly extinct, having been swamped by the steady progress towards the coast of the Mende tribes (which belong linguistically to the Mandingo group). All that we knew of Bulom prior to Mr. Thomas's conscientious work was derived from the records of Koelle and of Nyländer, an Anglican missionary who compiled an imperfect grammar and vocabulary of Bulom a hundred years ago. Temne, on the other hand, had been illustrated not only by Koelle (who alone has dealt with its exceedingly interesting

Digitized by Google

western dialects), but in a thorough-going fashion by another Anglican missionary with a German name, Schlenker. Mr. Thomas's work, however, in Temne, as in Bulom, is quite original, and is most useful in enabling us to understand the structure and phonology of these two forms of Semi-Bantu speech, and moreover represents them as they are spoken to-day. Mr. Thomas will probably quarrel with me for the frequent announcement that Temne and Bulom are "Semi-Bantu." He does not take up such a decided line himself, any more than he has done about some of the Semi-Bantu languages he was the first to illustrate in the Cross River basin. But I claim the right to be more dogmatic, since I have had of late opportunities of dealing somewhat thoroughly with the Semi-Bantu languages and their affinities with the Bantu, and have come to the conclusion (foreshadowed many years ago by the great philologist, Bleek) that Temne and Bulom, like the languages of Portuguese Guinea, Togoland, and Eastern Nigeria, must be classed as Semi-Bantu.

Vol. i. of Mr. Thomas's work deals with the laws and customs of the Mendi, Gõla, Kisi, Konô, Timne, Lokô, Limba, Yalunka, Koranko, Vai, and Susu peoples. (I quote his spelling, not always mine.) This volume contains excellent photographs of ethnic types. Another volume deals generally with the languages of Sierra Leone (besides Temne and Bulom): the Krim, Kisi, Limba dialects, Susu, Koranko, Yalunka, Konô, Vai, Mende, Lokô, and Fula. This will be particularly valuable for its treatment of the little-known and unclassified Limba (the speech of an interesting cattle-keeping tribe) and Lokô. Lokô, I fancy, has not been written down before.

I might state, in conclusion, that Mr. Thomas's work requires careful study and digestion before one can theorise from it.

H. H. JOHNSTON.

## AMERICAN NATURE-STUDY.

(1) *The Life of Inland Waters.* An elementary text-book of freshwater biology for American students. By Prof. James G. Needham and J. T. Lloyd. Pp. 438. (New York: The Comstock Publishing Co., 1916.) Price 3 dollars.

(2) *Wild Flowers of the North American Mountains.* By Julia W. Henshaw. Pp. 383. (London and New York: McBride, Nast and Co., Ltd., 1916.) Price 10*s.* 6*d.* net.

(3) *Hitting the Dark Trail, Starshine through Thirty Years of Night.* By Clarence Hawkes. Pp. 191. (London: George G. Harrap and Co., 1916.) Price 3*s.* 6*d.* net.

(1) PROF. J. G. NEEDHAM, of Cornell University, and his colleague, Mr. J. T. Lloyd, have prepared an introduction to the study of freshwater organisms—their adaptations, associations, and economic possibilities. The subject is an interesting one, the authors are enthusiasts and experts; the book should certainly give a stimulus to limnology. After dealing with the physical and chemical conditions of the freshwater environment, and its relation to the land-surface, the authors discuss the various types of lakes and ponds, of streams, of marshes, swamps, and bogs, and the difference between high and low water in each case. Then comes a vivid, well-illustrated survey of the freshwater plants and animals. The subject of adaptations is also very successfully handled. Flotation is helped by the outgrowth of slender prolongations and by the production of oils, gases, and jelly. Movement is facilitated by the "stream-line form" familiar in fishes. Animals living near the shore have adaptations for avoiding silt, for burrowing, for making shelters, for withstanding the rush of water. Seasonal vicissitudes are circumvented by adaptations for lying low, such as statoblasts, ephippia, and hibernacula. The secondary adaptation of originally terrestrial types to aquatic life is also discussed. Inter-organismal adaptations find fine illustrations in the bladderwort and in the dependence of the larvæ of freshwater mussels on fish hosts. This leads on to associations or societies, whether in the open-water (limnetic) or by the shores (littoral), the latter being again divided into still-water (lenitic) and rapid-water (lotic) societies. The studies end up with a suggestive chapter on water-culture, which is not too dismally utilitarian. As an elementary introduction to a fascinating study the book is admirable—clear, interesting, educative, and of moderate size. It is abundantly illustrated, and many of the figures have had brains put into their construction.

(2) Mrs. Henshaw has done good service in compiling a convenient flora of the North American mountains by means of which travellers can get to know a little about the characteristic alpine flowers. A terse diagnosis is given of each species, and then follow less formal descriptive notes in which there is occasionally a breeze of enthusiasm rather unusual in "Floras." The arrangement is popular—mainly according to colour—but there is a scientific classification as well. There are sixty-four fine photographs and seventeen beautiful coloured plates.

(3) The author of "Hitting the Dark Trail" was accidentally blinded by bird-shot when a boy of fourteen, and the book tells with delightful frankness and simplicity how he has made a success of his life in the true sense. The "menace of the years," as Henley called it, found him unafraid, and in spite of grim difficulties and discouragements he has remained "master of his fate and captain of his soul." Not only so; he has been able to trade with the visual gains of his early years, when he got a good grounding in woodcraft, and to get for himself and to give to many others a great deal of pleasure out of thirty years of Nature-study without eyes. Mr. Hawkes has written a number of popular "animal biographies"; he has now essayed the more difficult task of writing his own. He succeeds considerably by being perfectly natural. The autobiography reveals a fine quality of pluck, to reward which ought not to tax the resources of American civilisation.

## THE KINETIC THEORY REVIVED.

*The Dynamical Theory of Gases.* By J. H. Jeans. Second edition. Pp. vii + 436. (Cambridge: At the University Press, 1916.) Price 16*s.* net.

MORE than eleven years have elapsed since the first edition of this work was reviewed in NATURE (April 27, 1905). Most of the pioneers of the attempted rigorous mathematical theory have passed away, and the attempt to reconcile Boltzmann's minimum theorem with the properties of an aggregate of perfectly reversible units may be said to have been abandoned. On the other hand, the recently developed quantum hypothesis has, to some extent, had the opposite effect of leading us to believe that something more than the equations of reversible dynamics is needed to account for the phenomena of Nature. Equipartition may be characteristic of molecular systems, but the celestial universe shows no tendency towards Maxwell's law, and would probably refuse to obey it even if started according to this distribution.

The plan which Prof. Jeans now adopts in his book is probably the best one in the circumstances. The kinetic theory cannot be proved mathematically, neither can the data determined from a *calculable* mathematical theory be made to serve as more than approximations to the results of experiments. Thus arises a school of slipshod students of physics, who, when they cannot prove a result mathematically, state that it "has been shown experimentally," and if they cannot get their experiments to verify they state that it "may be proved" (from theory). This danger is largely obviated by the division of the earlier chapters into four sections, entitled "Mathematical Theory of a Gas in a Steady State," "Physical Properties of a Gas in a Steady State," "Mathematical Theory of a Gas not in a Steady State," "Physical Phenomena of a Gas not in a Steady State."

Among the miscellaneous applications it is interesting to note Prof. Jeans's remarks on the rate of escape of gases from planetary atmospheres. It will be remembered that the late Dr. Johnstone Stoney attempted to account for the loss of gases by the motion of the molecules which describe hyperbolic orbits under the attraction of the primary; and by assuming the absence of a particular gas from a particular member of the system he deduced the absence of other gases from other systems. It was, however, subsequently shown that, under the assumptions made by Dr. Stoney, the gases in question would not escape, and Dr. Stoney advanced the opinion that the methods of the kinetic theory on which his own investigations were based were inapplicable to the problem to which he had applied them. According to Prof. Jeans's views, hydrogen does not at present escape, but it did so when the earth was at a far higher temperature than at present. On the other hand, the brief discussion on our existing knowledge regarding the upper and lower regions of the atmosphere will help to reconcile theory with experiment.

The book thus contains as much information as an ordinary physics honours student can profitably study. But, of course, this is nothing like the whole of the kinetic theory, whether studied mathematically or experimentally.

G. H. B.

## MENDELISM ON THE FARM.

*A Manual of Mendelism.* By Prof. James Wilson. Pp. 152. (London: A. and C. Black, Ltd., 1916.) Price 2*s.* 6*d.* net

PROF. WILSON has prepared an exposition of Mendelism which will be of special interest to stock-breeders and serious students of agriculture. It is a model of clearness and directness, and bears the marks of the teacher as well as of the investigator. After explaining Mendel's experiments, his rule and his theory, the author passes to a discussion of various disturbing causes which account for abnormal distributions of characters. Thus there are cases in which the effects of the individual factors cannot be identified separately; cases of the suppression of the effect of one factor by that of another; cases of incomplete or absent dominance; cases where a factor is believed to combine indifferently with more than one other; cases where two or more factors seem to be linked together so that they are handed on from generation to generation as one; and cases in which two different factors produce a similar effect.

These are some of the reasons for results which are not typically Mendelian, and they might have been added to. Thus it has been convincingly shown by Morgan and others that environmental and developmental influences may have a profound effect on the outcome of Mendelian factor-differences. Prof. Wilson goes on to illustrate the improvements which have rewarded careful experimentation, *e.g.* as regards yield of wheat and of milk. That Mendelian formulæ can be used towards an increased production of material wealth has been proved by the results of workers like Nilsson-Ehle and Pearl, and these are but indications of what might be achieved. The average yield of wheat in Britain is about 32 bushels to the acre; it might be raised to 40 or even 50 bushels. "For every day by which the life of a variety of wheat is shortened between seed-time and harvest, the wheat-growing area in Canada reaches fifty or sixty miles farther northwards."

The work done in Denmark shows how the wealth of Britain, so far as it proceeds from dairy cattle, might be very nearly doubled. Those who wish to know how such exceedingly desirable results can be attained will be well advised if they study a book like Prof. Wilson's. It will show them how they may act with circumspection and foresight. The book would have been the better for pictures and its terse style is perhaps a trifle severe, but it is a book for the times, competently and carefully executed, which those whom it especially concerns should run to read.

## HIGHWAY ENGINEERING.

*Elements of Highway Engineering.* By Prof. A. H. Blanchard. Pp. xii+514. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1915.) Price 12*s.* 6*d.* net.

THE rapid development of mechanically propelled road vehicles during the past twenty years has brought about a complete revolution both in the construction and maintenance of roads, and the question of the development of the public road system has again, after years of neglect, become a problem of national importance. Motor vehicles are no longer mainly used for pleasure purposes; they are now an indispensable adjunct to almost every business, and for the economical working of motor lorries good road surfaces, and roads correctly laid out in regard to grade, are indispensable. Mr. Blanchard's book, which has been written as a text-book for engineering students as well as a reference book for engineers, is a welcome addition to the literature of this branch of engineering practice.

The first three chapters are devoted to an historical review of the subject, to a brief account of the systems of road administration in Europe and the United States, and to the preliminary investigations which must be made before an engineer can design satisfactory and economical highways. The fourth chapter treats of the necessary survey work in laying out urban and country roads, and of the preparation of the plans. The next chapter is devoted to the problems of grading, drainage, and, most important of all, to the question of the foundations upon which the roadway is to be carried.

Earth roads, gravel roads, and broken-stone roads are then dealt with in order; the methods to be adopted in the construction of each class are described, and the question of maintenance is fully discussed. In the chapter on broken-stone roads the author explains in detail the modern methods of testing the suitability of various classes of rocks for road metal; more attention might with advantage be given in this country to the systematic testing of road materials.

The ninth chapter is devoted to a detailed account of the sources, characteristics, and physical and chemical properties of bituminous materials; the highway engineer will find information in this chapter of great value to him when considering the question of the utilisation of bituminous materials in any proposed road reconstruction work. The next three chapters explain fully how these bituminous materials are best employed for dust-preventive purposes on ordinary roads and in the construction of bituminous macadam pavements and bituminous concrete pavements; the mechanical plant required for these operations is described in detail.

In the next five chapters the author treats of asphalt, wood-block, brick, and stone-block city roadways, describing the latest methods of constructing each type of roadway and of the machinery and other appliances required for their economical and speedy construction.

The remainder of the book is devoted to a brief but valuable discussion of the relative advantages and disadvantages of various types of roadway, and to an account of the methods of constructing the side-walks, curbs, gutters, culverts, bridges, and other details of road construction.

The book is well illustrated and thoroughly up-to-date, and should prove a welcome addition to the reference library of every engineer engaged on roadway design, construction, and maintenance.

T. H. B.

## OUR BOOKSHELF.

*The Military Map: Elements of Modern Topography (French School of War).* Pp. vii+130. (London: Macmillan and Co., Ltd., 1916.) Price 2*s.* 6*d.* net.

IN this book the authors set out to discuss the topographical map which has been produced especially for military purposes, and to treat particularly of the French General Staff map on the scale of 1 : 80,000. An introduction deals with the general principles on which a survey is carried out, while five chapters are devoted to the representation of detail and relief, and to some information relating to the French 1 : 80,000 map.

It cannot be said that the result is satisfactory as an introduction to military topographical maps or as a description of the French map. The authors do not seem to have that practical acquaintance with topographical surveying which would have enabled them to avoid several mistakes which occur, and render the book misleading for a beginner. The statement in the introduction that in triangulation the actual angles of the plane triangle formed by three stations are measured could not have been made by anyone who had used a theodolite, and is quite misleading as describing an operation in which horizontal angles are determined. Map projections are not satisfactorily treated, and at least the respective merits and demerits of those which are instanced might have been given. The retention of French terms is stated in the preface to be intentional, but it would have made the book much easier to read if after once quoting the French term the English equivalent had been employed, and a glossary of the French terms added as an appendix; as it is, many existing English terms do not appear, and some new ones are coined for which there is no need.

The relief of the ground is attributed to certain portions of the soil having sunk while others have been lifted, but no suggestion of the modelling of the surface by erosion appears. In treating of relief, the theoretical principles of contours and hachures are given, but in practice these are not strictly followed, and the reasons for the modifications should be given; the use of colour is not alluded to. Orientation in the field is the subject of the last chapter, but in advocating the use of the watch for this purpose, the error which may be introduced at different times and places should have been carefully explained.

H. G. L.

Digitized by Google

*Commercial Egg-Farming: From Practical Experiences gained over a Period of Years.* By S. G. Hanson. Pp. 62. (London: Constable and Co., Ltd.) Price 1*s.* net.

"I AM not a poultry-farmer because I like hens, but simply because I do not know how to earn an equal income so easily in any other way." So says the author on p. 10. This fact alone should secure for the work the serious consideration of all poultry-keepers. It is a good book containing much information and no padding. We should, however, have liked more detail on several points, and are far from convinced as to the economic side of the large brooder-house.

We note there is no balance-sheet. The cost of rearing pullets, even Leghorns, appears almost too modest at 2*s.* 6*d.* per head; and colony houses at about 2*l.* each (p. 39) also seems scarcely sufficient.

We like the author's capital charge of 1*l.* per bird, and this agrees with our own estimates and experience. No figures are given covering labour, rent, rates, and depreciation, considerable items on large plants.

The book is well worth reading, being full of hints, and the figures on the income side do not appear to be exaggerated; but it must be remembered that there are many drones in a large flock, and it is on the elimination of these that ultimate success depends. Although we are far from convinced as to the desirability of dry-mash feeding, there is much to be said in its favour on the score of economy of labour.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### Observations on the Excitation of Helium Spectra.

IN the course of an examination of the properties of the electron discharge in an atmosphere of helium we have made some observations of the conditions affecting the excitation of the lines of the helium spectra which seem to be of considerable interest. The source of electrons was an incandescent tungsten filament, and the discharge passed to a parallel nickel wire about 8 mm. distant. The electrodes were mounted in a quartz tube filled with helium at about 2 mm. pressure. The helium was free from all contaminants except a small amount of mercury vapour, the partial pressure of which was about 0·001 mm. in the observations immediately following.

In a particular experiment the current across the gap increased slowly from zero to 10 microamperes as the potential difference between the anode and the negative end of the filament was raised from 0 to 20 volts. The current then increased more rapidly to 100 microamperes at 23 volts, when the arc spectrum of mercury flashed out and the helium spectrum flashed out. With higher potentials most of the lines in the helium spectrum increased in intensity and the current increased, but at a gradually diminisning rate, to 1450 microamperes at 40 volts.

In other experiments the helium spectrum has been found to be excited by 22·5 volts potential difference. If allowance is made for the initial kinetic energy of the electrons and for the drop of potential down the filament due to the heating current, this quantity is not increased by so much as one volt, and there are indications that it tends to approach a lower limit close to the ionisation potential value for helium found by Franck and Hertz and by Pawlow. In any event, the observations made would seem to destroy the special significance of the value (approximatelv 30 volts) of the minimum potential difference necessary to excite the line spectra of helium given by Rau. There is no doubt that these spectra can be excited by the impact of electrons having energies much less than the value of the ionisation energy of helium calculated by Bohr. We are unable to reconcile these results with Bohr's theory except on the hypothesis that the impact ionisation of helium is a more complex phenomenon than has been supposed. Possibilities which suggest themselves are that the ionisation is the result of successive impacts or results from impacts on atoms in an abnormal condition caused by the absorption of radiation generated in other atoms in consequence of electron impact. Experiments to test these possibilities are in preparation.

In contrast to the lines of the mercury arc spectrum the different helium lines behave differently *inter se* when the exciting voltage is changed. Thus the blue line 4472 requires about half a volt, and the blue line 4713 about a quarter volt more potential difference for excitation than the yellow line. The green line 4922 of the first subsidiary series of parhelium seems to appear and disappear along with the blue line 4472 of the first subsidiary series of helium. The order of excitation with voltage for the different lines is not simply a question of frequency, but depends partly on the series to which the lines belong. Most of the lines increase steadily in intensity with increasing voltage and current density, but the line 4713 of the second subsidiary series of helium increases rapidly in intensity to a maximum soon after excitation, then becomes very faint as the potential difference is increased to about 40 volts, reappears with higher voltages, and then increases steadily in intensity with rising potential difference. Several of these effects have been noted by Rau at higher voltages.

We have examined the radiation from the helium spectrum in the extreme ultra-violet when excited by 40 to 70 volts potential difference, using a photoelectric method, and have obtained definite indications of the presence of radiations having wave-lengths close to 600 and to 400 Ångstrom units respectively.

## A TREATISE ON ELECTRICITY.[1]

IN the treatise on electricity referred to below the author aims at the production of "an advanced text covering both the theoretical and practical sides of the subject, so far as this can conveniently be done in a single volume." A somewhat obscure statement in the preface informs us that "though complete in itself, the book is not intended for beginners, who may be supposed to have read one of the excellent elementary treatises available, such as Whetham's 'Theory of Experimental Electricity.'" As a matter of fact, the first half of the book contains a curious combination of advanced mathematics and elementary physics. In the present state of our public-school education, in which it is possible for a boy to complete his school course with practically no knowledge of elementary science, such a combination may be necessary. This part of the treatise might therefore be recommended to a mathematical honours student taking up for the first time the study of electricity.

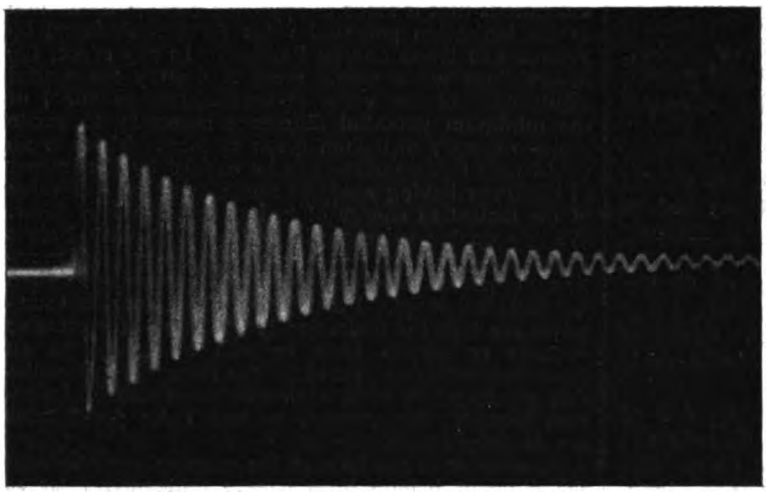

FIG. 1.—Damped Oscillatory Discharge. Photographed by Prof. J. Zenneck. From "A Treatise on Electricity."

In the first chapter, which is a mathematical introduction, the author discusses the transformation of Gauss, the theorems of Green and of Stokes, the equation of wave-motion, and the Bessel functions. In the second chapter he gives an elementary description of the behaviour of magnets and the plotting of lines of force with iron filings. This and the seven chapters following have been kept fairly simple and are intended to contain all the principles necessary for a right appreciation of the subject. The author is to be congratulated on the freshness of his presentation even of familiar topics. Recent forms of apparatus are well described and illustrated, and some novel experiments are introduced. The method of exhibiting lines of electric force by scattering small crystals of oxalic acid on a cardboard sheet is interesting, and the result is well shown in Fig. 38.

We notice that the term "electromotive force" (p. 110) is used as equivalent to "difference of potential." In our opinion this is a mistake; it is better to consider the E.M.F. as that which gives rise to a P.D. Thus in a cell on open circuit the E.M.F. due to the chemical action of the constituents sets up a P.D. between the terminals which, inside the cell, is opposed to the E.M.F. When the terminals are joined by a conductor the P.D. between the terminals falls, but the E.M.F. of the cell (neglecting polarisation) remains the same. In other cases an E.M.F. may arise from thermal effects or electromagnetic induction.

One difficulty which always perplexes a student of electricity is the significance of "magnetic induction," B. It was with a certain amount of pleasurable anticipation that we referred to Mr. Pidduck's treatment of this subject, only to be confronted by the bald statement: "The vector B is called the *magnetic induction*, and the last equation may be written $B = H + 4\pi I$, where addition signifies addition of rectangular components." It is true that the reader is assured that he will appreciate the full importance of the vector B after reading the next chapter, dealing with the induction of currents, but an appreciation of its importance is not the same as a clear realisation of its meaning. It is a remarkable fact that the term "permeability" is not mentioned in the index, nor does it appear to be once referred to in the text.

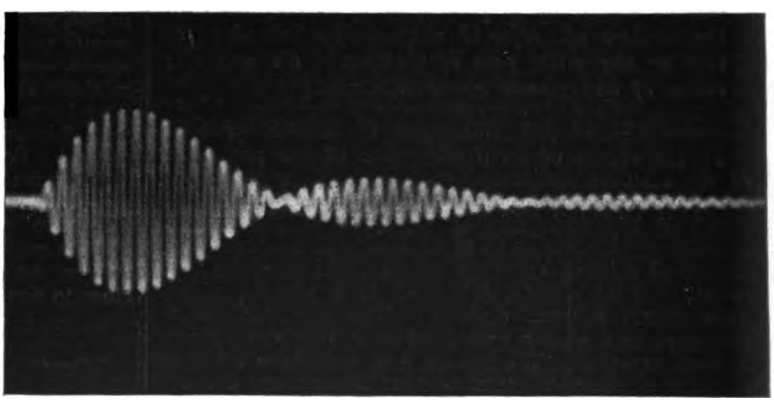

FIG. 2.—Beats in the Oscillatory Discharge of the Secondary of a Coupled Circuit. From a photograph by Prof. J. Zenneck. From "A Treatise on Electricity."

The latter half of the book, containing chapters which form introductory accounts of special

[1] "A Treatise on Electricity." By F. B. Pidduck. Pp. xiv+646. (Cambridge: At the University Press, 1916.) Price 14s. net.

Digitized by Google

subjects, is sure to prove of great service to advanced students. A valuable chapter on applied electricity is introduced, in which is a welcome section on the harmonic analysis of curves. The chapter on electric oscillations is one of the best in the volume. Prof. J. Zenneck's photographs of oscillatory discharges, two of which are here reproduced by the courtesy of the publishers, are excellent, as are the descriptions of the laboratory experiments that may be carried out in illustration of various branches of the subject. In a footnote to p. 444 is found a reference to the fact that the ratio of the electromagnetic to the electrostatic unit of charge has the dimensions of a velocity, followed by the startling statement: "The theory of electrical dimensions is otherwise of little interest." In view of the practical advantage to be gained by testing the dimensions of the terms of an equation and the stress laid recently on the principle of similitude or dynamical similarity, such an attitude cannot be justified.

In the chapter on the conduction of electricity through gases the author is scarcely fair to research carried out in this country. The corpuscular view of the kathode rays seems to have been advanced first by Varley in 1871, and the investigations of Sir W. Crookes surely deserve further description. In the account of the measurement of the ratio of the charge to the mass for the kathode particles Mr. Pidduck is less than just to the work of Schuster described in his second Bakerian lecture (1890) and to the experiments of Sir J. J. Thomson shown in a lecture delivered before the Royal Institution (*Electrician*, May 21, 1897). Kaufmann's paper was communicated to the *Annalen* on the same date. Wiechert's earlier experiments, "which did not go beyond the previous work of other observers" ("The Progress of Physics," Schuster, p. 68, 1911), were described in a lecture delivered on January 7, 1897. The experiments of Richardson and Compton in America on the photo-electric effect were carried out almost at the same time as those of Hughes at Cambridge. Millikan has just shown that it is possible to get very accurate values for Planck's constant, $h$, by the use of this method. A useful summary of fundamental physical quantities is given on p. 513. The name "Boltzmann's constant" is assigned by the author to the constant of molecular energy, $\alpha$. It is usual to give this name to the entropy constant, $k$, which has a value $\frac{2}{3}\alpha$.

The concluding chapters deal with radioactivity, as exhibited by radium and its derivatives, and the mathematical theory of electrons. The illustrations include a number of C. T. R. Wilson's remarkable cloud photographs showing the tracks of ionising particles in gases.

H. S. A.

## EGYPTIAN ASTRONOMY AND THE ZODIAC.

IN a recent number of the *Bulletin de l'Institut Français d'Archéologie Orientale* (cxii.) of Cairo, M. Georges Daressy, one of the foremost among French Egyptologists, treats of the knowledge of the constellations in ancient Egypt. His article is entitled "L'Egypte Céleste," by which words he means the duplication of the geography of the Nile valley into the sky, for the priests mentally projected another Egypt into the northern heavens. By a kind of symbolic celestial geography the daily solar journey was considered as a descent or voyage of the sun upon a river, the duplicate of the Nile, but situate in the firmament.

This conception having been evolved, to render the allegory geographically complete, it became necessary to have a series of "nomes," or counties, alongside the celestial river upon the banks, the district deities of which should correspond with those of similar sites through which the terrestrial Nile wended its way. For this purpose they selected the path of the ecliptic and identified that with the Nile's course. Precisely as each Nilotic "nome" possessed its own deity with his, or her, special totem symbol, so the Egyptian "wise men" provided parallel deity figures for their celestial river upon which the sun voyaged. With this object they adopted the zodiacal signs—the decans, the planets, and various constellations—because they required stellar associations, not only for the forty-two

Double zodiac of the French Archæological Institute at Cairo.

Digitized by Google

"nomes," but also for more than one temple, or important shrine, and its attendant city in many of the "nomes."

The event which induces M. Daressy to publish the fruits of his erudition upon this subject is the publication by him of a bronze zodiac with a series of two rows of twelve figures, the outer zone being the familiar zodiacal signs, and the inner, twelve animal symbols, attributable, Egyptologists think, to the twelve forms or phases assigned to the sun during his twelve hours' journey. These, in the earthly Egyptian gazetteer, are assigned to twelve of the twenty districts of Lower Egypt. This newly found double zodiac is very valuable for the explanation it affords of the symbols of the constellations upon the Denderah zodiac, because all these figures are intermingled in the large central circular disc, mixed up with deity figures representing the planets and certain prominent high-magnitude stars and the decans.

It should be stated that the zodiacs designed, and hitherto found, in Egypt are not of great antiquity. The arrangement of their symbols and of figurative objects for some constellations has certainly been produced under Greek influence. They appear to emanate from the Egyptian priests uniting their old stellar figure mythologies to the astronomical astrology of the Alexandrian school. Both parties, however, must at the date of the composition of these zodiacs have been acquainted with the Chaldean science of the heavens, derivations from which appear in the Old Testament and early Greek classics and art.

The deity symbols upon the Babylonian boundary stones are almost always astral and frequently zodiacal. Since the large increase in number of these monuments found at Susa, we have a much more complete series of the symbols.

Thus upon the stele of Melishipak we have the figure of an archer with the upper part human and the lower part that of a double-headed horse and two tails; those of a horse and a scorpion; also wings. This representation agrees almost completely with the Sagittarius of the Denderah zodiac, and with this Sagittarius the scorpion is associated in both cases.

This assimilation of Mesopotamian astronomy is identical with the adoption by the Egyptians of several Babylonian legends of the gods into Egyptian mythology. These exploits were foisted upon the deeds of Egyptian deities. For example, the Izdubar (Hercules) legends were in some cases introduced into the conflicts of Horus.

The parallels between terrestrial Egyptian geography and the places of the stars must, however, have been very old in Egypt, though not anterior to the era of Menes. M. Daressy ingeniously

In addition to the famous zodiac from Denderah, now in the Louvre, we have, among others, the new one at Cairo, the planisphere and tableaux carved on the hypostyle hall at Denderah, copies of others once at Esneh and Erment, and the coffin of Hern-netch-tep in the British Museum.

JOSEPH OFFORD.

## THE PREVENTION OF COLLISION AT SEA.[1]

PROF. JOLY proposes, in the work before us, that sound, which travels at different rates through different fluids, should be utilised for navigational purposes as well as for the prevention of collision. The rate of travel of sound through air—viz. 1090 ft. per sec. at a temperature of 32° F. (zero C.), or 1100 ft. per sec. at a temperature of 52° F. (11·1 C.)—has long been utilised in H.M. naval surveying service for measuring bases in places where it is not possible to land, owing to the coast being covered with mangrove growth. The system in use is to fire a small mortar which has a plug driven in its muzzle and to note the time which elapses between the flash of the discharge and the report of the mortar. For this purpose a chronometer watch which beats five times for every two seconds of time is used, and it will be evident that each beat of the watch represents 440 ft., so that if the observer makes a mistake in counting the beats a corresponding error will be the result in the length of the base.

This method of ascertaining distance has also been used to ascertain the distance off a cliffy coast when sailing along it. In H.M.S. *Actæon*, when sailing along the coast of Russian Tartary, which has very few distinctive marks, a gun was fired at intervals and the beats of the watch counted until the echo was heard. Half the time elapsed gave the distance off.

In the case of sound travelling through water the rate is much more rapid, and that rate depends on temperature as well as on the density. In river water the rate is 4714 ft. per sec. at a temperature of 55° F. (13° C.), and of 5013 ft. per sec. at a temperature of 86° F. (30° C.), whilst in sea-water, at a temperature of 68° F. (20° C.), its rate is 4761 ft. per sec., but where the specific gravity of the water is increased, as in the Mediterranean or Red Sea, the time will be different. In thick weather, therefore, when the flash of a gun cannot be seen, the distance off can be ascertained by noting the number of beats between the receipt of a sound travelling through water and one through the air, provided they are emitted simultaneously. This difference is 4·25 secs. for each nautical mile the observer is

Digitized by Google

beats be counted between the receipt of the radiotelegraphic message and the subsequent reports through the water and the air, the distance can be ascertained and checked, observing that an error of the beat means 440 ft. in air, but in water an error of one beat means an error of 1900 ft.

If sound signals could be implicitly relied on they would be a still greater aid to the seaman than they now are, for they are used at present both in air and water to warn vessels—in air by bells, guns, and sirens, and in water by submarine bells—but, unfortunately, they are not absolutely to be relied on, for experiment has shown that areas of silence occur sometimes in the vicinity of the localities where sound signals are emitted through the air, and that signals emitted through water may be deflected or reflected by obstruction. But further experiments are required before a definite opinion can be pronounced on their accuracy, and especially experiments on the rate of travel of sound through ocean water of different densities and temperatures. Experiments seem also to be needed in crowded thoroughfares as to whether sound-signals are or are not masked by more than one vessel emitting them. In addition, experiments are desirable with reference to the conveyance of sound through the water from shore stations: (1) What means should be taken to send the signal? (2) Will waves beating on the shore, especially on a rocky coast, interfere with the signal?

It is a great advantage to seamen that men of science should direct their attention to investigating problems of this nature, and it is to be hoped that Prof. Joly's work may cause the subject to be taken up and some further experiments made on the points which are still uncertain; but the book as it is is well worthy to be studied by all navigators.

It only remains to point out that it is a simple matter to draw a curve which will tell at a glance the distance from a station emitting simultaneous signals. If the beats of the watch be used as ordinates and tenths of miles as abscissæ, three curves can be drawn, one showing the distance off by the time elapsed between the flash of a gun, or the receipt of a radiotelegraphic signal, and the sound conveyed through the air; another, of the distance off by the time elapsed between the flash of a gun, or the receipt of a radiotelegraphic signal, and the sound conveyed through the water; and a third by the time elapsed between the two sounds, one conveyed by air, and the other by the water.

## *PROF. T. G. BRODIE, F.R.S.*

DEEP regret is felt by many men of science at the death of Prof. Brodie, which occurred suddenly (from heart failure) at the early age of fifty on August 20. He was not only pre-eminent in the scientific world, but had endeared himself in a quite exceptional way to his numerous pupils, colleagues, and friends. The world is indeed poorer by his loss, and the tragic suddenness in being cut off in his prime adds an unusual pathos to the event.

Prof. Brodie was born at Northampton, and was the second son of the Rev. A. Brodie, Vicar of Grandborough. He was educated at King's College School and St. John's College, Cambridge. He received his medical education at King's College, London, and after a brilliant academic career there and taking his degree of M.D. at the London University, he became demonstrator of physiology at his alma mater, and devoted his life thenceforth to this branch of science. He then became in turn senior demonstrator of physiology at the London Hospital and lecturer in the same subject at St. Thomas's Hospital. While still a student he commenced research work, and his earliest paper on Muscular Elasticity still remains authoritative. So closely was his name connected with original research, and so numerous were his papers on both the chemical and physical side of physiology, that when Prof. Sims Woodhead relinquished his directorship of the laboratories of the Royal Colleges of Surgeons and Physicians, London, for his chair at Cambridge, Brodie was immediately chosen as his successor, and he held the post with distinction and success until the Royal Colleges, as a measure of economy, decided to maintain their laboratories no longer. So fruitful had been the work carried out and inspired by Brodie in this position that in 1904 he received his F.R.S. Then came an interval in which Brodie filled simultaneously three posts—namely, the lectureship on physiology at the London School of Medicine for Women, the professorship of physiology at the Royal Veterinary College, and the professor superintendentship of the Brown Animal Sanatory Institute. This triple part meant overwhelmingly hard work, but it did not stop Brodie's researches, and it was only because each post was so poorly paid that it was necessary. England often treats her scientific sons thus, and it is much to be regretted that a man of such distinction should have been obliged to seek a position and salary worthy of his gifts in a colonial university. It was in 1908 that Brodie accepted the chair of physiology at Toronto, and London's loss was Canada's gain.

Prof. Brodie used to revisit London every long vacation, and during these so-called holidays he was always hard at work at research. It was during this time that his famous work on the kidney was carried out, and his Croonian lecture at the Royal Society dealt with one aspect of his investigations on this subject. Soon after the outbreak of war he became a captain in the Canadian medical service, and in this position undertook valuable research work on questions arising out of the war: such as respiratory effects, and the means of re-educating maimed men to become useful members of society.

As a teacher he was most successful; as a writer he was a little slow, but always sure and lucid; his unpublished manuscripts will be brought to light later; as a personal friend he was loyal, straightforward, and true.

Digitized by Google

His widow and three fine sons survive to mourn his loss; his funeral at Hampstead on August 23 was a military one, and was largely attended not only by his relations and personal friends, but by representatives, military and medical, of both British and Canadian institutions.

## *SCIENTIFIC AND INDUSTRIAL RESEARCH.*[1]

THE important Report before us embodies the first annual statement of the work of the Advisory Council. Its contents deserve the closest consideration by all who have been interesting themselves in the dominating questions of the organisation of scientific and industrial research. We hope to deal more in detail with the proposals and suggestions in the Report in a later issue. Meanwhile, it will be sufficient to point out that it is divided into sections which are occupied respectively with:—

(i) The statement of the problems at issue and the steps taken by the Advisory Council to inform itself as to the present condition of scientific research in the United Kingdom and the bodies or persons conducting it.

(ii) The standing committees appointed on special subjects and the co-operative action undertaken by trade associations and professional and learned societies.

(iii) The nature of the difficulties surrounding the organisation of scientific and industrial research.

(iv) The sphere of action of the universities and technical colleges and the probable necessity for special research institutions.

(v) The necessity for conjoint action by all portions of the Empire and a general statement of the conditions of successful work.

The general tone of the Report may be described as tentative; the Council evidently desiring to feel its way cautiously and yet desiring to utilise so far as possible at present the existing machinery of research.

Taken as a whole, the Report is a very able statement of the complexity of the questions awaiting solution, and its recommendations should receive the most careful thought from all who are concerned with scientific work, whether pure or applied.

The report occupies fifty-six pages, of which forty are devoted to the report of the Advisory Council, signed by the administrative chairman, Sir William McCormick. In an introductory note Lord Crewe refers to the establishment in July, 1915, of the Committee of the Privy Council for Scientific and Industrial Research, and to grants made on the advice of the Advisory Council. Twenty scientific investigations were in progress at the end of March, 1916, and the cost of the establishment of the scheme was 25,000*l.* for the financial year 1915–16, and of this 12,241*l.* was expended, including a grant of 4250*l.* to the Royal Society. For the current financial year the vote by Parliament is 40,000*l.*

A memorandum embodying certain suggestions for promoting co-operation between different parts of the Empire in the organisation of scientific and industrial research is printed as an appendix. Approval is expressed of the principle of Imperial co-operation; and it is suggested that each Overseas Government which is willing to enter into such an arrangement should constitute some body or agency having functions analogous to those of the Advisory Council which acts for the United Kingdom. The Committee of Council is prepared to co-operate with the Secretary of State in establishing and conducting any central organisation which it may be found desirable to set up in London for the purpose of facilitating and carrying on the business of an Imperial Scheme of Research.

The report of the Advisory Council opens with an historical statement in which reference is made to the establishment of the National Physical Laboratory, the Engineering Standards Committee, the Imperial Institute, the Imperial College of Science and Technology, and other national institutions. At the outset the Council decided to give science in its applications to industry precedence over pure science, though under no misapprehension as to the relations between pure and applied science. Conferences were held with a number of professional bodies, and standing committees were appointed on engineering, metallurgy, and mining, while others are contemplated. A register of researches is being prepared, and encouragement is being given to co-operative research to benefit an industry as a whole. The most promising sign of progress is the increased interest in scientific research now manifested by men of business, manufacturers, and trade associations, but much yet remains to be done on a larger scale than has hitherto been attempted. The small scale on which most British industrial firms have been planned is one of the principal impediments in the way of the organisation of research, with a view to the conduct of these long and complicated investigations which are necessary for the solution of the fundamental problems lying at the basis of our staple industries.

It is intended to issue, under the title of "Science and Industry," a new series of pamphlets showing among other matters what is being done in industrial research laboratories in the United States and elsewhere. One of these will include material collected by Mr. A. P. M. Fleming, and another the paper by Dr. C. E. Kenneth Mees, printed in NATURE of July 13 and 20. Some of the conditions to be secured if the object for which the Committee of Council was established is to be attained are summarised as follows:—

If we were asked to state these conditions in the shortest possible terms we should reply: First, a largely increased supply of competent researchers; secondly, a hearty spirit of co-operation among all concerned, men of science, men of business, working men, professional and scientific societies, universities

Digitized by Google

is adequately rewarded. But it is also true that a supply will create a demand, and since the Committee of Council was established in order to encourage a demand for research, we are anxious to see a sufficient supply of trained workers forthcoming to enable a reasonable start to be made on the new road when peace is restored. Before the war the output of the universities was altogether insufficient to meet even a moderate expansion in the demand for research. The annual number of students graduating with first and second class honours in science and technology (including mathematics) in the universities of England and Wales before the war was only about 530, and of these but a small proportion will have received any serious training in research. We have frequently found on inquiry that the number of workers of any scientific standing on a given subject of industrial importance is very limited.

It is in our view certain that the number of trained research workers who will be available at the end of the war will not suffice for the demand that we hope will then exist. We are too apt to forget in this country that with industry as with war a brilliant group of field officers, and even a well-organised general staff, need armies of well-trained men in order to produce satisfactory results. Our people have no reason to fear or envy the scientific pioneers of other races. They have had, and will probably continue to have, their full share of the outstanding minds to which each century gives birth, but as time goes on the sphere of the solitary worker tends to become relatively, if not absolutely, smaller. Effective research, particularly in its industrial applications, calls increasingly for the support and impetus that come from the systematised delving of a corps of sappers working intelligently, but under orders. We have not yet learned how to make the most of mediocre ability—particularly in things of the mind—yet without the scientific rank and file it will be as impossible to staff the industrial research laboratories which are coming, as to fight a European war with seven divisions. There is as much place and need for plodding labour in scientific research as in other kinds of work.

The responsibility for dealing with the grave situation which we anticipate, rests with the education departments of the United Kingdom. We shall be able to do something to encourage a longer period of training by the offer of research studentships and the like; but that will not suffice. It is useless to offer scholarships if competent candidates are not forthcoming, and they cannot be forthcoming in sufficient numbers until a larger number of well-educated students enter the universities. That is the problem which the education departments have to solve, and on the solution of which the success of the present movement in our opinion largely depends.

As regards the second condition of success, progress in co-operative effort is undoubtedly being made in many directions, and we have mentioned some instances of it. But we wish to point out that there are specially strong reasons for more co-operation between the various British firms in each industry and between the industries and the State in the furtherance of research. The particular difficulties encountered in the day-to-day routine of manufacture, the possibility of improving [illegible] continuous effort. The firm that starts out upon this quest must either be very powerful or it must find the necessary strength in association with others. If the general level of manufacture can be rapidly raised by co-operative effort in the exchange of information between firms, and in the support of national trade institutes for research, as well as in the improvement of the conditions and efficiency of labour, this country will have gone far towards establishing its industrial prosperity on a firm basis.

There is already a certain number of large firms in this country who, realising the unity of interest between employers and employed, have systematically striven to raise the standard of living among their workers and to give them a direct interest in the firm's success. Some of these efforts have not been philanthropic; and where they have been so in intention, they have been proved by experience not to require any such spur. But the small firm finds it as difficult to provide pensions or clubs as to pay for research laboratories or original workers. We believe that some form of combination for both purposes may be found to be essential if the smaller undertakings of this country are to compete effectively with the great trusts and combines of Germany and America.

The economic problem lies outside our province, but it is an important aspect of the great issue with which we are concerned, and we do not believe that issue can be met effectively unless a co-ordinated advance is made simultaneously on the whole front. We think it possible that the voluntary efforts of manufacturers in friendly union which enabled the problem of munitions to be rapidly solved may lead to a new kind of reciprocity between firms which will avoid the evils both of monopoly and of individualism. We think that as people have learnt to combine against the risks of fire or shipwreck without losing either initiative or freedom, so firms may come to look upon expenditure for research as a necessary kind of insurance. It is certain that the costs to be met will, on any adequate estimate, have to be counted, not by tens of thousands nor even by hundreds of thousands.

Quite apart from this general and fundamental point of view, team-work is needed, because when we come to deal with the great industries which have an output worth many millions sterling a year and employ labour in proportionate amount, the problems to be solved are too manifold, and too complicated, to be dealt with by individual firms, or even, we may add, by a Government department. The coal-winning industry, the textile industries, the steel industry, the great engineering and shipbuilding industries, the rubber industry, need research on a scale which calls for the financial and intellectual assistance of all parties concerned. When co-operation has done all that is possible in the common interest, there will still remain a mass of research work to be done by individual firms in their own interests, which will amply repay the cost and effort.

We have repeatedly spoken in the pages of this report about the initiation of particular researches, and the solution of particular problems. It has been the inevitable concomitant of the line of procedure we have advisedly selected. But if it is supposed that modern industry can be developed or even maintained

Digitized by Google

will often suggest a diverging inquiry that, if followed up, may produce results even more valuable than the original question. Such loose ends litter the laboratories of firms which confine themselves to questions of the moment. They lead straight to the basic theory of a subject, to the roots that strike down into pure science. They are infinite in number and interminable, as the man of pure science knows well; but they also often yield results that revolutionise those industries which are empirical in their methods—as what industry is not?—and give that control over nature which it is the object of all science, whether pure or applied, to secure. The discovery of the structure of the indigo molecule led not merely to the synthetic manufacture of this blue dye, but has enabled the chemist to produce a number of new substances of analogous structure and different shades of colour.

Research of this order does not cease when a problem—even if it be as complicated as synthetic indigo—has been solved. It must be continuous in its operation, and its ramifications will spread as knowledge grows. It will inevitably tend to bring industries into intimate relation, which are at present independent of each other, to transform what have hitherto been crafts into scientific industries, and to require co-operation not only between different firms in the same industry, but between groups of industries in a continuously widening series of inter-related trades.

## *THE BRITISH ASSOCIATION AT NEWCASTLE.*

APPARENTLY, the handbook published in connection with the meeting of the British Association, which is being held this week in Newcastle-upon-Tyne, has been well received by the members. Unlike the handbooks for previous Newcastle meetings, the present one describes not only the industries of the district but also includes articles embracing the remarkable and interesting archæology and history of Northumbria. If there is any fault to be found with its contents it is that no more than a passing reference is made in its pages to two widely known scientific societies—viz., the North-East Coast Institution of Engineers and Shipbuilders and the North of England Institute of Mining and Mechanical Engineers, which have their headquarters in Newcastle and have for nearly half a century done exceptionally useful work, whereas a whole article is devoted to the history of the Literary and Philosophical Society, which is little more than a lending library. The anomaly is more remarkable when one remembers that the handbook has been issued for the information of the members of an association founded for the advancement of science. However, the editors are to be congratulated on producing a useful handbook. Those members of the Association who visit the Roman wall near Chollerford and the ancient buildings in Newcastle should find many of the articles of great interest.

Members of the Association who attended the previous meetings in Newcastle and are there this week will have a further opportunity of studying the characteristics of the North-country people. In workers in the Tyne munition factories. When the general holiday was announced, the local committee feared that the further depletion in the number of cabs and other conveyances resulting from the holiday would mean that the bulk of the number of visitors would be put to considerable inconvenience on their arrival. By the action of the North-Eastern Railway Company, however, who placed special vehicles for luggage at the disposal of the members, and assisted in other ways, no such inconvenience was experienced.

It is expected, too, that the other preparations for the meeting are being appreciated by the members. On Monday and Tuesday last the reception room presented that animated appearance which is associated with the opening days of a British Association Meeting. The posters and signs in the streets erected for the guidance of visitors incidentally exhibit the coping-stone of the successful work done by the Sectional Arrangements Committee.

For some time previous to the opening days of the meeting a good deal of interest was shown locally in the forecasts of the activities of the sections, and in the announcements with regard to the President's address and the evening discourses. It was not surprising, therefore, on Tuesday evening last to see that in a larger audience than was expected the local residents were well represented.

In addition to the exhibitions forming part of the programme, to which attention has been directed in previous numbers of NATURE, an attractive and useful exhibition of chemicals and apparatus is being held in the College of Medicine. The main object of the exhibition is to demonstrate the progress made by British firms in manufacturing articles formerly produced in Germany only. In the Hancock Museum, also, an exhibition of geological and botanical interest is being held.

INAUGURAL ADDRESS (ABRIDGED) BY SIR ARTHUR EVANS, D.LITT., LL.D., P.S.A., F.R.S., EXTRAORDINARY PROFESSOR OF PREHISTORIC ARCHÆOLOGY, OXFORD, CORRESPONDANT DE L'INSTITUT DE FRANCE, ETC., PRESIDENT.

### *New Archaeological Lights on the Origins of Civilisation in Europe: its Magdalenian forerunners in the South-West and Ægean Cradle.*

THE science of antiquity depends on evidence and rests on principles indistinguishable from those of the sister science of geology. Its methods are stratigraphic. As in that case the successive deposits and their characteristic contents—often of the most fragmentary kind—enable the geologist to reconstruct the fauna and flora, the climate and physical conditions, of the past ages of the world, and to follow out their gradual transitions or dislocations, so it is with the archæologist in dealing with unwritten history.

In recent years—not to speak of the revelations of Late Quaternary culture on which I shall presently have occasion to dwell—in Egypt, in Babylonia, in Ancient Persia, in the Central Asian deserts, or,

Digitized by Google

of former civilisation, the very existence of which was formerly unsuspected. Even in later periods archæology, as a dispassionate witness, has been continually checking, supplementing, and illustrating written history. It has called back to our upper air, as with a magician's wand, shapes and conditions that seemed to have been irrevocably lost in the night of Time.

The investigations of a brilliant band of prehistoric archæologists, with the aid of representatives of the sister sciences of geology and palæontology, have brought together such a mass of striking materials as to place the evolution of human art and appliances in the last Quaternary period on a far higher level than had even been suspected previously. Following in the footsteps of Lartet, and after him Rivière and Piette, Profs. Cartailhac, Capitan, and Boule, the Abbé Breuil, Dr. Obermeier, and their fellow-investigators have revolutionised our knowledge of a phase of human culture which goes so far back beyond the limits of any continuous story, that it may well be said to belong to an older world.

To the engraved and sculptured works of man in the "Reindeer period" we have now to add not only such new specialities as are exemplified by the moulded clay figures of life-size bisons in the Tuc d'Audoubert Cave, or the similar high reliefs of a procession of six horses cut on the overhanging limestone brow of Cap Blanc, but whole galleries of painted designs on the walls of caverns and rock shelters.

So astonishing was this last discovery, made first by the Spanish investigator, Señor de Sautuola—or rather his little daughter—so long ago as 1878, that it was not until after it had been corroborated by repeated finds on the French side of the Pyrenees—not, indeed, until the beginning of the present century—that the Palæolithic age of these rock-paintings was generally recognised. In their most developed stage, as illustrated by the bulk of the figures in the Cave of Altamira itself, and in those of Marsoulas in the Haute Garonne, and of Font de Gaume in the Dordogne, these primeval frescoes display not only a consummate mastery of natural design, but an extraordinary technical resource. Apart from the charcoal used in certain outlines, the chief colouring matter was red and yellow ochre, mortars and palettes for the preparation of which have come to light. In single animals the tints are varied from black to dark and ruddy brown or brilliant orange, and so, by fine gradations, to paler nuances, obtained by scraping and washing. Outlines and details are brought out by white incised lines, and the artists availed themselves with great skill of the reliefs afforded by convexities of the rock surface. But the greatest marvel of all is that such polychrome masterpieces as the bisons, standing and couchant, or with limbs huddled together, of the Altamira Cave, were executed on the ceilings of inner vaults and galleries where the light of day has never penetrated. Nowhere is there any trace of smoke, and it is clear that great progress in the art of artificial illumination had already been made. We now know that stone lamps, decorated in one case with the engraved head of an ibex, were already in existence.

Such was the level of artistic attainment in South-Western Europe, at a modest estimate some ten thousand years earlier than the most ancient monusign had already clearly pointed to the existence of huts or wigwams; the "scutiform" and other types record appliances yet to be elucidated, and another sign well illustrated on a bone pendant from the Cave of St. Marcel has an unmistakable resemblance to a sledge.[1] But the most astonishing revelation of the cultural level already reached by primeval man has been supplied by the more recently discovered rock-paintings of Spain. The area of discovery has now been extended there from the Province of Santander, where Altamira itself is situated, to the Valley of the Ebro, the Central Sierras, and to the extreme south-eastern region, including the Provinces of Albacete, Murcia, and Almeria, and even to within the borders of Granada.

One after another, features that had been reckoned as the exclusive property of Neolithic or later ages are thus seen to have been shared by Palæolithic man in the final stage of his evolution. For the first time, moreover, we find the productions of his art rich in human subjects. At Cogul the sacral dance is performed by women clad from the waist downwards in well-cut gowns, while in a rock-shelter of Alpera,[2] where we meet with the same skirted ladies, their dress is supplemented by flying sashes. On the rock-painting of the Cueva de la Vieja, near the same place, women are seen with still longer gowns rising to their bosoms. We are already a long way from Eve!

It is this great Alpera fresco which, among all those discovered, has afforded most new elements. Here are depicted whole scenes of the chase, in which bowmen —up to the time of these last discoveries unknown among Palæolithic representations—take a leading part, though they had not as yet the use of quivers. Some are dancing in the attitude of the Australian Corroborees. Several wear plumed head-dresses, and the attitudes at times are extraordinarily animated. What is specially remarkable is that some of the groups of these Spanish rock-paintings show dogs or jackals accompanying the hunters, so that the process of domesticating animals had already begun. Hafted axes are depicted as well as cunningly-shaped throwing sticks. In one case at least we see two opposed bands of archers—marking at any rate a stage in social development in which organised warfare was possible —the beginnings, it is to be feared, of "kultur," as well as of culture!

Nor can there be any question as to the age of these scenes and figures, by themselves so suggestive of a much later phase of human history. They are inseparable from other elements of the same group, the animal and symbolic representations of which are shared by the contemporary school of rock-painting north of the Pyrenees. Some are overlaid by palimpsests, themselves of Palæolithic character. Among the animals actually depicted, moreover, the elk and bison distinctly belong to the Late Quaternary fauna of both regions, and are unknown there to the Neolithic deposits.

In its broader aspects this field of human culture, to which, on the European side, the name of Reindeer age may still on the whole be applied, is now seen to have been very widespread. In Europe itself it permeates a large area—defined by the boundaries of

Digitized by Google

of culture, the remains of which are by no means confined to the Cis-Saharan zone, where incised figures occur of animals like the long-horned buffalo (*Bubalus antiquus*) and others long extinct in that region. This southern branch may eventually be found to have a large extension. The nearest parallels to the finer class of rock-carvings as seen in the Dordogne are, in fact, to be found among the more ancient specimens of similar work in South Africa, while the rock-paintings of Spain find their best analogies among the Bushmen.

That there was a considerable amount of circulation, indeed—if not of primitive commerce—among the peoples of the Reindeer age is shown by the diffusion of shell or fossil ornaments derived from the Atlantic, the Mediterranean, or from inland geological strata. Art itself is less the property of one or another race than has sometimes been imagined—indeed, if we compare those products of the modern carver's art that have most analogy with the horn and bone carvings of the Cave men, and rise at times to great excellence—as we see them, for instance, in Switzerland or Norway—they are often the work of races of very different physical types. The negroid contributions, at least in the southern zone of this Late Quaternary field, must not be under-estimated. The early steatopygous images—such as some of those of the Balzi Rossi caves—may safely be regarded as due to this ethnic type, which is also pictorially represented in some of the Spanish rock-paintings.

The nascent flame of primeval culture was thus already kindled in that older world, and, so far as our present knowledge goes, it was in the south-western part of our continent, on either side of the Pyrenees, that it shone its brightest. After the great strides in human progress already made at that remote epoch, it is hard, indeed, to understand what it was that still delayed the rise of European civilisation in its higher shape. Yet it had to wait for its fulfilment through many millennia. The gathering shadows thickened and the darkness of a long night fell, not on that favoured region alone, but throughout the wide area where Reindeer man had ranged. Still the question rises—as yet imperfectly answered—were there no relay runners to pass on elsewhere the lighted torch?

Something, indeed, has been recently done towards bridging over the "hiatus" that formerly separated the Neolithic from the Palæolithic age—the yawning gulf between two worlds of human existence. The Azilian—a later decadent outgrowth of the preceding culture—which is now seen partially to fill the lacuna, seems to be in some respects an impoverished survival of the Aurignacian.[3] The existence of this phase was first established by the long and patient investigations of Piette in the stratified deposits of the Cave of Mas d'Azil in the Ariège, from which it derives its name, and it has been proved by recent discoveries to have had a wide extension. It affords evidence of a milder and moister climate—well illustrated by the abundance of the little wood snail (*Helix nemoralis*), and the increasing tendency of the reindeer to die out in the southern parts of the area, so that in the fabric of the characteristic harpoons deer-horns are used as substi-

The little flakes with a worked edge often known as "pygmy flints," which were most of them designed for insertion into bone or horn harpoons, like some Neolithic examples, are very characteristic of this stratum, which is widely diffused in France and elsewhere under the misleading name of "Tardenoisian." At Ofnet, in Bavaria, it is associated with a ceremonial skull burial showing the co-existence at that spot of brachycephalic and dolichocephalic types, both of a new character. In Britain, as we know, this Azilian, or a closely allied phase, is traceable as far north as the Oban Caves.

What, however, is of special interest is the existence of a northern parallel to this cultural phase, first ascertained by the Danish investigator, Dr. Sarauw, in the lake station of Maglemose, near the west coast of Zealand. Here bone harpoons of the Azilian type occur, with bone and horn implements showing geometrical and rude animal engravings of a character divergent from the Magdalenian tradition. The settlement took place when what is now the Baltic was still the great "Ancylus Lake," and the waters of the North Sea had not yet burst into it. It belongs to the period of the Danish pine and birch woods, and is shown to be anterior to the earliest shell mounds of the Kitchen-midden people, when the pine and the birch had given place to the oak. Similar deposits extend to Sweden and Norway, and to the Baltic Provinces as far as the Gulf of Finland. The parallel relationship of this culture is clear, and its remains are often accompanied with the characteristic "pygmy" flints. Breuil, however,[4] while admitting the late Palæolithic character of this northern branch, would bring it into relation with a vast Siberian and Altaic province, distinguished by the widespread existence of rock-carvings of animals. It is interesting to note that a rock-engraving of a reindeer, very well stylised, from the Trondhjem Fjord, which has been referred to the Maglemosian phase, preserves the simple profile rendering—two legs only being visible—of Early Aurignacian tradition.

It is a commonplace of archæology that the culture of the Neolithic peoples throughout a large part of Central, Northern, and Western Europe—like the newly domesticated species possessed by them—is Eurasiatic in type. So, too, in southern Greece and the Ægean world we meet with a form of Neolithic culture which must be essentially regarded as a prolongation of that of Asia Minor.

It is clear that it is on this Neolithic foundation that our later civilisation immediately stands. But in the constant chain of actions and reactions by which the history of mankind is bound together—short of the extinction of all concerned, a hypothesis in this case excluded—it is equally certain that no great human achievement is without its continuous effect. The more we realise the substantial amount of progress of the men of the Late Quaternary age in arts and crafts and ideas, the more difficult it is to avoid the conclusion that somewhere "at the back of behind"—it may be by more than one route and on more than one continent, in Asia as well as Africa—actual links of connection may eventually come to light.

Digitized by Google

self, fully panoplied from the head of Zeus. The indebtedness to Oriental sources was either regarded as comparatively late or confined to such definite borrowings as the alphabet or certain weights and measures. Egypt, on the other hand, at least until Alexandrine times, was looked on as something apart, and it must be said that Egyptologists on their side were only too anxious to preserve their sanctum from profane contact.

A truer perspective has now been opened out. It has been made abundantly clear that the rise of Hellenic civilisation was itself part of a wider economy and can be no longer regarded as an isolated phenomenon. Indirectly, its relation to the greater world and to the ancient centres to the south and east has now been established by its affiliation to the civilisation of prehistoric Crete and by the revelation of the extraordinarily high degree of proficiency that was there attained in almost all departments of human art and industry. That Crete itself—the "Mid-Sea land," a kind of half-way house between three continents—should have been the cradle of our European civilisation was, in fact, a logical consequence of its geographical position. An outlier of mainland Greece, almost opposite the mouths of the Nile, primitive intercourse between Crete and the further shores of the Libyan Sea was still further facilitated by favourable winds and currents. In the eastern direction, on the other hand, island stepping-stones brought it into easy communication with the coast of Asia Minor, with which it was actually connected in late geological times.

But the extraneous influences that were here operative from a remote period encountered on the island itself a primitive indigenous culture that had grown up there from immemorial time. In view of some recent geological calculations, such as those of Baron De Geer, who by counting the number of layers of mud in Lake Ragunda has reduced the ice-free period in Sweden to 7000 years, it will not be superfluous to emphasise the extreme antiquity that seems to be indicated for even the later Neolithic in Crete. The *Hill* of Knossos, upon which the remains of the brilliant Minoan civilisation have found their most striking revelation, itself resembles in a large part of its composition a great mound or Tell—like those of Mesopotamia or Egypt—formed of layer after layer of human deposits. But the remains of the whole of the later ages represented down to the earliest Minoan period (which itself goes back to a time contemporary with the early dynasties of Egypt—at a moderate estimate to 3400 B.C.) occupy considerably less than a half—19 ft., that is, out of a total of more than 45. Such calculations can have only a relative value, but, even if we assume a more rapid accumulation of débris for the Neolithic strata and deduct a third from our calculation, they would still occupy a space of more than 3400 years, giving a total antiquity of some 9000 years from the present time.[5] No Neolithic section in Europe can compare in extent with that of Knossos, which itself can be divided by the character of its contents into an Early, Middle, and Late phase. But its earliest stratum already shows the culture in an advanced stage, with carefully ground and polished axes and finely burnished pottery. The beginnings of Cretan Neolithic must go back to a still more remote antiquity. The [illegible] of the Neolithic [illegible]

branch belongs to a vast province of primitive culture that extended from southern Greece and the Ægean islands throughout a wide region of Asia Minor and probably still further afield.

An interesting characteristic is the appearance in the Knossian deposits of clay images of squatting female figures of a pronouncedly steatopygous conformation and with hands on the breasts. These in turn fit on to a large family of similar images which recur throughout the above area, though elsewhere they are generally known in their somewhat developed stage, showing a tendency to be translated into stone, and finally—perhaps under extraneous influences both from the north and east—taking a more extended attitude. These clearly stand in a parallel relationship to a whole family of figures with the organs of maternity strongly developed that characterise the Semitic lands, and which seem to have spread from there to Sumeria and to the seats of the Anau culture.

At the same time this steatopygous family, which in other parts of the Mediterranean basin ranges from prehistoric Egypt and Malta to the north of mainland Greece, calls up suggestive reminiscences of the similar images of Aurignacian man. It is especially interesting to note that in Crete, as in the Anatolian region where these primitive images occur, the worship of a mother goddess predominated in later times, generally associated with a divine Child—a worship which later survived in a classical guise and influenced all later religion. Another interesting evidence of the underlying religious community between Crete and Asia Minor is the diffusion in both areas of the cult of the Double Axe. This divine symbol, indeed, or "Labrys," became the special emblem of the palace sanctuary of Knossos itself, which owes to it its traditional name of Labyrinth. I have already directed attention to the fact that the absorptive and disseminating power of the Roman Empire brought the cult of a male form of the divinity of the Double Axe to the Roman Wall and to the actual site on which Newcastle stands.

The fact should never be left out of sight that the gifted indigenous stock which in Crete eventually took to itself on one hand and the other so many elements of exotic culture was still deep-rooted in its own. It had, moreover, the advantages of an insular people in taking what it wanted and no more. Thus it was stimulated by foreign influences but never dominated by them, and there is nothing here of the servility of Phœnician art. Much as it assimilated, it never lost its independent tradition.

It is interesting to note that the first quickening impulse came to Crete from the Egyptian and not from the Oriental side—the Eastern factor, indeed, is of comparatively late appearance. My own researches have led me to the definite conclusion that cultural influences were already reaching Crete from beyond the Libyan Sea before the beginning of the Egyptian dynasties. These primitive influences are attested, amongst other evidences, by the forms of stone vessels, by the same æsthetic tradition in the selection of materials distinguished by their polychromy, by the appearance of certain symbolic signs, and the subjects of shapes and seals which go back to prototypes in use among the "old race" of the Nile Valley. The impression of a very active agency indeed is so strong that the possibility of some actual

Digitized by Google

monument of a Middle Empire Egyptian was found in the palace court at Knossos. More surprising still are the cumulative proofs of the reaction of this early Cretan civilisation on Egypt itself, as seen not only in the introduction there of such beautiful Minoan fabrics as the elegant polychrome vases, but in the actual impress observable on Egyptian art even on its religious side. The Egyptian griffin is fitted with Minoan wings. So, too, on the other side, we see the symbols of Egyptian religion impressed into the service of the Cretan nature goddess, who in certain respects was partly assimilated with Hathor, the Egyptian cow-goddess of the underworld.

My own most recent investigations have more and more brought home to me the all-pervading community between Minoan Crete and the land of the Pharaohs. When we realise the great indebtedness of the succeeding classical culture of Greece to its Minoan predecessor the full significance of this conclusion will be understood. Ancient Egypt itself can no longer be regarded as something apart from general human history. Its influences are seen to lie about the very cradle of our own civilisation.

The high early culture, the equal rival of that of Egypt and Babylonia, which thus began to take its rise in Crete in the fourth millennium before our era, flourished for some two thousand years, eventually dominating the Ægean and a large part of the Mediterranean basin. To the civilisation as a whole I ventured, from the name of the legendary King and lawgiver of Crete, to apply the name of "Minoan," which has received general acceptance; and it has been possible now to divide its course into three ages—Early, Middle, and Late, answering roughly to the successive Egyptian kingdoms, and each in turn with a triple subdivision.

It is difficult indeed in a few words to do adequate justice to this earliest of European civilisations. Its achievements are too manifold. The many-storeyed palaces of the Minoan priest-kings in their great days, by their ingenious planning, their successful combination of the useful with the beautiful and stately, and, last but not least, by their scientific sanitary arrangements, far outdid the similar works, on however vast a scale, of Egyptian or Babylonian builders. What is more, the same skilful and commodious construction recurs in a whole series of private mansions and smaller dwellings throughout the island. Outside "broad Knossos" itself, flourishing towns sprang up far and wide on the country-sides. New and refined crafts were developed, some of them, like that of the inlaid metal-work, unsurpassed in any age or country. Artistic skill, of course, reached its acme in the great palaces themselves, the corridors, landings, and porticoes of which were decked with wall-paintings and high reliefs, showing in the treatment of animal life not only an extraordinary grasp of nature, but a grandiose power of composition such as the world had never seen before. Such were the great bull-grappling reliefs of the Sea Gate at Knossos and the agonistic scenes of the great palace hall.

The modernness of much of the life here revealed to us is astonishing. The elaboration of the domestic arrangements, the staircases storey above storey, the front places given to the ladies at shows, their fashionable flounced robes and jackets, the gloves sometimes seen on their hands or hanging from their folding chairs, their very mannerisms as seen on the frescoes, pointing their conversation with animated gestures—how strangely out of place would it all appear in a classical design! Nowhere, not even at Pompeii, have more living pictures of ancient life been called up for us than in the Minoan palace of Knossos. The touches supplied by its closing scene are singularly dramatic—the little bath-room opening out of the Queen's parlour, with its painted clay bath, the royal draught-board flung down in the court, the vessels for anointing and the oil-jar for their filling ready to hand by the throne of the priest-king, with the benches of his consistory round and the sacral griffins on either side. Religion, indeed, entered in at every turn. The palaces were also temples, the tomb a shrine of the Great Mother. It was perhaps owing to the religious control of art that among all the Minoan representations—now to be numbered by thousands—no single example of indecency has come to light.

A remarkable feature of this Minoan civilisation cannot be passed over. I remember that at the Liverpool meeting of this association in 1896—just before the first results of the new discoveries in Crete were known—a distinguished archæologist took as the subject of an evening lecture, "Man before Writing," and, as a striking example of a high culture attained by "*Analfabeti*," singled out that of Mycenæ—a late offshoot, as we know now, from Minoan Crete. To such a conclusion, based on negative evidence, I confess I could never subscribe—for had not even the people of the Reindeer age attained to a considerable proficiency in expression by means of symbolic signs? To-day we are able to trace the gradual evolution on Cretan soil of a complete system of writing from its earliest pictographic shape, through a conventionalised hieroglyphic to a linear stage of great perfection. In addition to inscribed sealings and other records some two thousand clay tablets have now come to light, mostly inventories or contracts; for though the script itself is still undeciphered, the pictorial figures that often appear on these documents supply a valuable clue to their contents. The numeration also is clear, with figures representing sums up to 10,000. The inscribed sealings, signed, counter-marked, and counter-signed by controlling officials, give a high idea of the elaborate machinery of government and administration under the Minoan rulers.

The minutely organised legal conditions to which this points confirm the later traditions of Minos, the great law-giver of prehistoric Crete, who, like Hammurabi and Moses, was said to have received the law from the God of the Sacred Mountain. The clay tablets themselves were certainly due to Oriental influences, which make themselves perceptible in Crete at the beginning of the Late Minoan age, and may have been partly resultant from the reflex action of Minoan colonisation in Cyprus. From this time onwards Eastern elements are more and more traceable in Cretan culture, and are evidenced by such phenomena as the introduction of chariots—themselves perhaps more remotely of Aryan-Iranian derivation—and by the occasional use of cylinder seals.

Simultaneously with its Eastern expansion, which affected the coast of Phœnicia and Palestine as well as Cyprus, Minoan civilisation now took firm hold of mainland Greece, while traces of its direct influence are found in the West Mediterranean basin—in Sicily, the Balearic Islands, and Spain. At the time of the actual Conquest and during the immediately succeeding period the civilisation that appears at Mycenæ and Tiryns, at Thebes and Orchomenos, and at other centres of mainland Greece, though it seems to have brought with it some already assimilated Anatolian elements, is still in the broadest sense Minoan. It is only at a later stage that a more provincial offshoot came into being to which the name Mycenæan can be properly applied. But it is clear that some vanguard at least of the Aryan Greek immigrants came into con-

Digitized by Google

tact with this high Minoan culture at a time when it was still in its most flourishing condition. The evidence of Homer itself is conclusive. Arms and armour described in the poems are those of the Minoan prime, the fabled shield of Achilles, like that of Herakles described by Hesiod, with its elaborate scenes and variegated metal-work, reflects the masterpieces of Minoan craftsmen in the full vigour of their art; the very episodes of epic combat receive their best illustration on the signets of the great days of Mycenæ. Even the lyre to which the minstrel sang was a Minoan invention. Or, if we turn to the side of religion, the Greek temple seems to have sprung from a Minoan hall, its earliest pediment schemes are adaptations from the Minoan tympanum—such as we see in the Lions' Gate—the most archaic figures of the Hellenic goddesses, like the Spartan Orthia, have the attributes and attendant animals of the great Minoan Mother.

Some elements of the old culture were taken over on the soil of Hellas. Others which had been crushed out in their old centres survived in the more Eastern shores and islands formerly dominated by Minoan civilisation, and were carried back by Phœnician or Ionian intermediaries to their old homes. In spite of the overthrow which about the twelfth century before our era fell on the old Minoan dominion and the onrush of the new conquerors from the North, much of the old tradition still survived to form the base for the fabric of the later civilisation of Greece. Once more, through the darkness, the lighted torch was carried on, the first glimmering flame of which had been painfully kindled by the old cave-dwellers in that earlier Palæolithic world.

The Roman Empire, which in turn appropriated the heritage that Greece had received from Minoan Crete, placed civilisation on a broader basis by welding together heterogeneous ingredients and promoting a cosmopolitan ideal. If even the primeval culture of the Reindeer age embraced more than one race and absorbed extraneous elements from many sides, how much more is that the case with our own, which grew out of the Greco-Roman! Civilisation in its higher form to-day, though highly complex, forms essentially a unitary mass. It has no longer to be sought out in separate luminous centres, shining like planets through the surrounding night. Still less is it the property of one privileged country or people. Many as are the tongues of mortal men, its votaries, like the Immortals, speak a single language. Throughout the whole vast area illumined by its quickening rays, its workers are interdependent, and pledged to a common cause.

We, indeed, who are met here to-day to promote in a special way the cause of truth and knowledge, have never had a more austere duty set before us. I know that our ranks are thinned. How many of those who would otherwise be engaged in progressive research have been called away for their country's service! How many who could least be spared were called to return no more! Scientific intercourse is broken, and its cosmopolitan character is obscured by the death struggle in which whole continents are locked. The concentration, moreover, of the nation and of its Government on immediate ends has distracted it from the urgent reform[illegible]

knowledge in our schools and colleges is appreciably less than elsewhere. So, too, with the scientific side of education, it is not so much the actual amount of science taught that is in question—insufficient as that is—as the instillation of the scientific spirit itself—the perception of method, the sacred thirst for investigation.

But can we yet despair of the educational future of a people that has risen to the full height of the great emergency with which they were confronted? Can we doubt that, out of the crucible of fiery trial, a New England is already in the moulding?

We must all bow before the hard necessity of the moment. Of much we cannot judge. Great patience is demanded. But let us, who still have the opportunity of doing so, at least prepare for the even more serious struggle that must ensue against the enemy in our midst, that gnaws our vitals. We have to deal with ignorance, apathy, the non-scientific mental attitude, the absorption of popular interest in sports and amusements.

And what, meanwhile, is the attitude of those in power—of our Government, still more of our permanent officials? A cheap epigram is worn threadbare in order to justify the ingrained distrust of expert, in other words of scientific, advice on the part of our public offices. We hear, indeed, of "Commissions" and "Inquiries," but the inveterate attitude of our rulers towards the higher interests that we are here to promote is too clearly shown by a single episode. It is those higher interests that are the first to be thrown to the wolves. All are agreed that special treasures should be stored in positions of safety, but at a time when it might have been thought desirable to keep open every avenue of popular instruction and of intelligent diversion, the galleries of our National Museum at Bloomsbury were entirely closed for the sake of the paltriest saving—three minutes, it was calculated, of the cost of the war to the British Treasury! That some, indeed, were left open elsewhere was not so much due to the enlightened sympathy of our politicians, as to their alarmed interests in view of the volume of intelligent protest. Our friends and neighbours across the Channel, under incomparably greater stress, have acted in a very different spirit.

It will be a hard struggle for the friends of science and education, and the air is thick with mephitic vapours. Perhaps the worst economy to which we are to-day reduced by our former lack of preparedness is the economy of truth. Heaven knows!—it may be a necessary penalty. But its results are evil. Vital facts that concern our national well-being, others that even affect the cause of a lasting peace, are constantly suppressed by official action. The negative character of the process at work which conceals its operation from the masses makes it the more insidious. We live in a murky atmosphere amidst the suggestion of the false, and there seems to be a real danger that the recognition of truth as itself a tower of strength may suffer an eclipse.

It is at such a time and under these adverse conditions that we, whose object it is to promote the advancement of science, are called upon to act. It is for us to see to it that the lighted torch handed down to us from the ages shall be passed on with a still

## NOTES.

THE Hon. Sir Charles Parsons, K.C.B., F.R.S., has been nominated as president of the British Association, the meeting of which is to be held at Bournemouth in September next.

THE annual autumn meeting of the Institute of Metals will be held on Wednesday, September 20, in the rooms of the Chemical Society, Burlington House, London. Sir George T. Beilby will preside, and a number of important metallurgical papers will be presented and discussed.

THE fourth annual meeting of the Indian Science Congress will be held at Bangalore on January 10–13. H.H. the Maharajah of Mysore has consented to be patron of the meeting, whilst Sir Alfred Bourne, K.C.I.E., F.R.S., will be the president. The following sectional presidents have been appointed:—Mr. J. MacKenna (Pusa), Agriculture and Applied Chemistry; the Rev. D. Mackichan (Bombay), Physics; Dr. Zia Ud-din Ahmad (Aligarh), Mathematics; Dr. J. L. Simonsen (Madras), Chemistry; Mr. K. Ramunni Menon (Madras), Zoology; Mr. C. S. Middlemiss (Calcutta), Geology. All communications relating to the congress should be addressed to Dr. Simonsen, the Presidency College, Madras.

GREAT satisfaction is felt by everyone in the news published in the *Daily Chronicle* on September 5 that Sir Ernest Shackleton had succeeded in rescuing the twenty-two members of his Antarctic expedition marooned on Elephant Island since April 15. Three previous attempts to reach the island were unsuccessful, but with characteristic persistence Sir Ernest continued his efforts to relieve the men, and sailed from Punta Arenas on August 26 in the *Yelcho*, a small Chilian steamer. On August 30, after steering in a fog through numerous stranded bergs, he reached Wild's camp at 1 p.m., and at 2 p.m. the vessel was homeward bound. On September 3 Punta Arenas was reached, and the message "All saved. All well," was dispatched to the *Daily Chronicle*, from which the following summary of Mr. Frank Wild's report is taken:—"On April 25, the day after the departure of the boat, the island was beset by dense pack-ice. The party was confined to a narrow spit of land, 250 yards long and 40 yards wide, surrounded by inaccessible cliffs and ice-laden seas. We were forced to abandon our ice-hole, which was made untenable by the snow. We made a dwelling of our two boats, supported by rocks, and set up as far as practicable from the sea. The weather continued appalling. In May a heavy blizzard swept much valuable gear into the sea. Fortunately, owing to the low temperature, an icefoot formed on the seashore, and this protection was the means of saving us from total destruction. From June onwards the weather was better as regards wind, but we were under a constant pall of fog and snow. At the beginning of August we were able to collect seaweed and limpets, which formed a valuable change in our diet, but the deep water, heavy seas, and ice prevented us from fishing. On August 28 the gale drove the ice-pack from the island, and on August 30, through the lifting fog, we caught sight of the *Yelcho* steering through a maze of stranded bergs. An hour later we were homeward bound." Sir Ernest Shackleton has announced the safe return of the party in a telegram to the King, who has replied:—"Most heartily rejoice that you have rescued your twenty-two comrades all well. Congratulate you on the result of your determined efforts to save them, and that success crowned your third attempt. I greatly admire the conduct of their leader, Frank Wild, which was so instrumental in maintaining their courage and hope. I trust you will soon bring them all safely home.—GEORGE R.I."

MR. R. W. DOYNE, who died at Oxford on August 30, was well known as an ophthalmologist. Born on May 15, 1857, educated at Marlborough and Keble College, Oxford, he became a naval surgeon, but early relinquished this work to specialise in ophthalmic practice. He returned to Oxford, and devoted his boundless energy and enthusiasm to the prosecution of his favourite study in that town and University. There he succeeded in founding the now flourishing Eye Hospital, and thanks to the munificence of the late Mrs. Ogilvie, obtained recognition of ophthalmology in the University, being himself appointed first Margaret Ogilvie reader in ophthalmology. The clinical material at Oxford is not large, but from the point of view of research the paucity of cases is not without its advantages, and was utilised by Doyne to the fullest extent. The inhabitants of the surrounding country districts are wedded to the soil, so that cases can be kept under observation for many years, and hereditary disorders can be traced through several generations. Doyne was thus enabled to study forms of hereditary cataract, etc., under the most favourable conditions, and thereby to contribute many valuable papers to the Transactions of the Ophthalmological Society. He was enthusiastic in ophthalmoscopic work, and ungrudging in spending money on having coloured drawings made of interesting fundus cases. His collection is extremely fine, and formed one of the attractions at the annual gathering of ophthalmologists which has for several years met at Oxford at his invitation, and is known as the Oxford Ophthalmological Congress. Doyne was very keen on sports, and his papers on "The Eye in Sport," dealing with such topics as the influence of visual acuity, binocular vision, and so on, in shooting, fencing, and other sports, are important, not only for the brilliant application of physiological facts to practical conditions, but also for the light they throw on visual phenomena themselves.

NEWS has just reached us of the death, on May 21, of Prof. J. A. Portchinsky, the distinguished Russian entomologist, at sixty-eight years of age. Prof. Portchinsky graduated in 1871 at the Natural History Faculty of the Petrograd University. He was conservator and librarian to the Russian Entomological Society, and between 1874 and 1894 occupied the post of its scientific secretary. In 1894 he was appointed member of the scientific committee of the Ministry of Agriculture, chief of the Entomological Bureau of this committee, and chief editor of its Memoirs, in which capacity he remained until his death. The number of these Memoirs of which he was himself the author amounts to twenty-four, besides a great number of articles and scientific papers published in many journals and periodicals. He travelled extensively over Russia, Caucasia, and Turkestan, and collected a mass of observations and materials on the biology of insects. He was also the reviewer of "Applied Entomology in Russia."

PROF. FERDINAND FISCHER, professor of chemical technology in the University of Göttingen, whose death, at the age of seventy-four, was recently announced, was born at Rodermühle a. Harz in 1842 and graduated at Jena in 1869, after previously studying both in Göttingen and in Berlin. In 1897 he was appointed to the chair at Göttingen, a position he occupied with conspicuous success for close upon twenty years, during which period he made valuable contributions to chemical technology, both by his

Digitized by Google

writings and by his experimental work. His investigations have been concerned chiefly with problems connected with solid and gaseous fuel, with the examination of water supplies, and with the analytical control of the Le Blanc soda and other industrial processes. In association with these inquiries he designed the many forms of apparatus which bear his name, of which that for accurate gas analysis, his modification of the Orsat apparatus, and his calorimeters for gaseous and for liquid fuel are the best known. Although these are, to a considerable extent, superseded to-day, they each mark an important advance in the construction of the apparatus used for these purposes, and successfully fulfilled the special objects for which they were designed. It is, however, principally as an author and as an editor that Fischer rendered his greatest service to the advancement of chemical technology. He revised and edited several editions of R. v. Wagner's standard textbook on chemical technology, which has been translated into many languages, including English, and from 1887 to 1910 he acted as editor, in succession to Wagner, of the invaluable "Jahresberichte der chemischen Technologie." Fischer's well-known treatise, "Die chemische Technologie der Brennstoffe," which was first published in 1880, and has passed through many editions since then, has always stood as an authoritative work on this branch of chemical technology, and his "Taschenbuch für Feuerungstechniker," which has also passed through many editions, has served as a most useful guide to technologists. Other publications have dealt with a variety of fuel problems and allied subjects, with the technology of water supplies, and with the study of chemical technology. Fischer also acted as editor of *Dingler's polytechnisches Journal* and of the *Zeitschrift für angewandte Chemie* for a number of years, and in 1887 he founded and edited the *Zeitschrift für die chemische Industrie*. Apart from these contributions to chemical literature, Fischer took a leading part in the establishment of the German Society for Applied Chemistry, which has since developed into the important Association of German Chemists.

IMPORTANT developments have taken place recently in connection with the work of the Corrosion Committee of the Institute of Metals, which for the last six years has been investigating the causes of corrosion of marine condenser tubes. In the first place the committee has been recognised by the Privy Council Committee for Scientific and Industrial Research, and has been enlarged so as to include representatives of several Government departments, including the Admiralty, Lloyd's Register, and the Board of Trade, and some of the leading engineering societies. As from October 1 next it will receive a grant of 900*l*. in aid of its work for the forthcoming year. Hitherto the experimental work has been under the charge of Dr. Bengough at the University of Liverpool. In future the experimental condenser plant will be installed and worked at the Southwick Electricity Generating Station of the Brighton Corporation, an arrangement which is due to the initiative and good offices of Mr. J. Christie, their municipal electrical engineer, and will enable the plant to be worked under conditions much more nearly approximating to "practical" than has been possible hitherto. Laboratory research work in connection with the same problem will be carried out by Drs. Bengough and Hudson in the metallurgical laboratories of the Royal School of Mines, South Kensington, which have been gratuitously placed at the disposal of the committee by the authorities.

IN 1902 Mr. A. Hrdlička published an account of all the crania of the Tenape or Delaware Indians which at that time were preserved in American museums. Since then fifty-seven skeletons have been discovered in the Upper Delaware River valley, and the same writer publishes in Bulletin No. 62 of the Bureau of American Ethnology an elaborate monograph describing this fresh material. To this he has added a general sketch of Eastern Indian crania in general. The most interesting result of the survey is that, while the Iroquois are regarded as a linguistic stock distinct from the Algonquian, the measurements of skulls of representatives of the two stocks show no such distinction. It is also evident that the eastern Algonquian and Iroquois Indians, while essentially of one type, approached purity of type much more in the north-eastern Atlantic States and in south-eastern Canada than further south. The Iroquois group was a complex of tribes, some of which are still poorly represented in American collections, and it is possible that more abundant material will exhibit some differences between these tribes owing to their varied earlier associations, and perhaps to other agencies, among which we may suspect that varieties of environment played an important part.

WILLIAM WILBERFORCE, who played such an important part in the abolition of slavery, was born in the fine old Elizabethan mansion in High Street, Hull, now known as Wilberforce House, which has been converted into a public museum and memorial of Wilberforce. Mr. T. Sheppard, the energetic curator, has succeeded in collecting a fine series of the numerous medals issued in connection with the abolition of slavery, and he describes them in No. 109 of the useful series of Hull Museum Publications. The first exhibit in the collection was issued in 1807, immediately on the abolition of the slave trade in the British Dominions, this being the precursor of the abolition of slavery itself in England some years later. The series closes with the medal issued by the Hull Corporation in 1906, when the museum was opened. The portrait of Wilberforce, a very pleasing one, was taken from a miniature in the possession of the Rev. J. B. Harford, son of the author of the Life of the statesman.

THE July issue of the *National Geographic Magazine* is entirely devoted to a description of Mexico, as usual illustrated by a fine series of photographs. The most interesting contribution is that by Mr. F. H. Probert, "The Treasure Chest of Mercurial Mexico," a description of the mining centre at Guanajuato, where silver was discovered by a peon at La Luz in 1554. Rayas, a few years later, discovered the mine which still bears his name, and in 1557 the Rayas and Mellado workings led to the recognition of the Veta Madre, the mother lode of Guanajuato, which has yielded untold riches. Cecil Rhodes prophesied of Mexico that "from her hidden vaults, her subterranean treasure-houses, will come the gold, silver, copper, and precious stones that will build the empires of to-morrow and make future cities of this world veritable New Jerusalems." The Veta Madre has already produced gold and silver to the value of more than a billion dollars, and, given the possibility of decent government, the prediction of Rhodes is sure to be fulfilled. The worst feature of the situation is the poverty and social degradation of the mining population.

AN interesting addition to the exhibits in the Insect Gallery of the Natural History Museum, South Kensington, has been made in the shape of a collection of

Digitized by Google

"trout-flies," presented by Mr. Martin H. Mosely. The collection consists of a series of the natural insects that serve as food for trout and grayling (preserved in formalin placed in shallow glass dishes), and along with them a series of the artificial insects which are made in imitation of the natural ones and used as bait by anglers.

THERE has been placed on exhibition in the Central Hall of the Natural History Museum, South Kensington, a small series of specimens illustrating the natural history of the worm, Bilharzia (Schistosomum), that causes the disease of the bladder and rectum, known as bilharziosis, common in Africa, the West Indies, and Japan. Actual specimens are shown of the worms as they occur in the veins of the intestine, and examples are shown of pond-snails which are known to harbour the alternate generation of the worms. The life-history of the worm is explained by means of drawings of the egg and the sporocyst and cercaria stages, and photographs of bilharzia-infected canals in Egypt, from Lieut.-Col. R. T. Leiper's report of 1915, are exhibited to illustrate how the disease may be communicated to human beings by bathing or standing in the infected water.

IN the *Zoologist* for August Dr. J. M. Dewar records a series of experiments on habit-formation in a queen wasp which had its nest at the end of a long tunnel opening into a disused rabbit burrow. The approach to the nest at the time of its discovery was made, not by the burrow, but through the tunnel. How she would behave when this tunnel was plugged was the task he set himself to discover. His observations lead him to the conclusion that "the learning of the wasp did not transcend the sensori-motor level, and that images or ideas were not elements essential to an explanation of the observed reactions." He attaches, apparently, no importance to the fact that when the wasp first found the entrance plugged she gained access to the nest by the burrow, about 50 cm. below the tunnel, and endeavoured to break away the plug from behind.

MR. R. GREENAWAY, in the *Zoologist* for August, comments at length on the inability of natural selection to explain certain various phases in the evolution of the protozoa. The protective coverings of Difflugia and Arcella among the Thecolobosa, or the addition of flagellæ in the Flagellata, he argues, cannot be explained by natural selection, since this would demand similar armature and locomotory organs in all the species of their respective types which are now living side by side in the same environment. He concludes, therefore, that these differences are to be explained, at least in part, by "some form of the orthogenesis theory."

OWING to the difficulty of obtaining material, the ovarian tissues of the Marsupialia have been very little studied. Thus the memoir which appears in the *Quarterly Journal of Microscopical Science* (No. 244, N.S., July), by Dr. C. H. O'Donoghue, will be extremely welcome. He describes at length the corporea lutea and the interstitial tissue of the ovary, his investigations, the author is able to show that the corpus luteum of the marsupial and the eutherian are indistinguishable, thus directly contradicting the statements made on this subject by Fraenkel and Cohn, and repeated without criticism by Van der Stricht.

IN Memoirs of the Geological Survey of New South Wales, Ethnological Series, No. 2, Mr. R. Etheridge, curator of the Australian Museum, Sydney, discusses the origin of the warrigal (*Canis dingo*), the name "dingo" being a contemptuous term applied by the aborigines to the white man's cur. He reviews the evidence collected by Sir F. McCoy and Mr. G. Krefft, who found its remains associated with a fauna now extinct. Mr. Etheridge adds to this that he thinks he has identified teeth of a dog somewhat larger than the warrigal among a quantity of jaw bones and loose teeth found in the Wellington Cave. He leaves the question of the origin and date of introduction in doubt, but the evidence here collected does not seem to conflict with the view that it was like the Indian pariah dog, and was brought by emigrants from the Malay region.

THE report on the investigation of rivers undertaken by the Royal and Royal Geographical Societies has been published by the latter society. The investigation, which was begun in 1906, had in view the examination of certain rivers in England and Wales for the purpose of ascertaining the volume of discharge, the suspended and dissolved matter in wet and dry periods and the total for the year, the erosion of the surface of the basin, the rainfall in each basin, and the extent occupied by calcareous and non-calcareous, and by pervious and impervious formations. The rivers selected for examination were the Exe, the Medway, and the Severn. These were selected as river basins representative of different geological conditions. Circumstances prevented the inclusion of the Salisbury Avon as a typical chalk river. The report is the work of various authors, including Dr. Aubrey Strahan, Mr. N. F. Mackenzie, Dr. H. R. Mill, and Dr. J. S. Owens. Attention was directed to the desirability of such investigations by the recent report of the Royal Commission on Canals and Inland Navigation, but the work requires to be carried on systematically throughout the country. The present report serves to indicate the value of such a survey of our water resources, and the lines on which it should be conducted.

IN the *Geographical Review* for July (vol. ii., No. 1) there is a paper by Messrs. W. G. Reed and H. R. Tolley, of the U.S. Department of Agriculture, on "Weather as a Business Risk in Farming." Climatic data expressed in averages afford a basis for determining the general character of a region, but the farmer requires to know the frequency or magnitude of departures from the average. Late spring and early autumn frosts do great harm to crops. The statement of the extreme dates of these frosts is of doubtful value in the determination of the risk of damage, as it is based on single occurrences. The authors have calculated the standard deviation from the average date of the last and first killing frosts, in spring

Digitized by Google

Griffith Taylor has, however, given some account of the initial experiments (Bulletin No. 13, Commonwealth Bureau of Meteorology). He points out that Melbourne is not suited for these experiments, since the prevailing northerly winds cause a large proportion of the balloons to be carried out to sea and lost, while those carried by the easterly upper-air movement to the Victorian mountains are seldom recovered. No conclusive results can be deduced from the meagre data at present available, but after the war experiments are to be conducted under more favourable conditions at the meteorological observatory at Mount Stromlo, in Federal territory.

DR. W. VAN BEMMELEN has published in English a very interesting account of the "Results of Registering Balloon Ascents at Batavia" (*Batavia Javasche Bockhandel en Drukkerij*, 1916). Batavia lies a few degrees south of the equator, and these observations are valuable on account of the obvious care that has been taken to ensure accuracy and also on account of the equatorial situation. The ascents were 103 in all, spread over the six years 1910–15, and sixty-six available records were obtained. Dr. van Bemmelen gives tables showing the temperature and humidity, and also discusses the annual and daily variations. The most striking result is the low temperature that is found at great heights in these equatorial regions. Eighteen ascents reached the stratosphere, the mean height of which is shown as just under 17 km. At sea-level the mean temperature is 26° C., the freezing point is reached at 4·7 km., at 10 km. the temperature is −34° C., compared with −51° C. in England, but at 17 km. over Batavia the low value of −84° C. is found, against −54° C. over England. On one occasion a temperature of −90·2° C. (183° A. or −130° F.) was reached at 16·7 km. If any doubt remained about the existence of these low temperatures over the equator it has been removed by the publication of these results. The value given at 17 km., viz. −84° C., is based on twenty observations, and the standard deviation is small, so that there is no room for serious error in this value.

THE Journal of the Society of Siberian Engineers (Tomsk, January, 1916) devotes an article, illustrated by climatological charts, to the possibility of extending and developing the beet-sugar industry in Siberia. The desirability of establishing this industry in Siberia was pointed out by the Russian Government thirty years ago, and substantial fiscal relief was offered to pioneers, with the result that the first factory was set up in 1889 in the Minusinsk district of the Government of Yenisei. The seat of the beet-sugar industry, the western provinces of Russia, being now in enemy occupation, there is among the refugees from those regions a large amount of highly skilled labour available for employment elsewhere. The present moment is therefore opportune for directing attention to the subject and taking practical steps to foster a growing industry the development of which is of the greatest importance for the future of Siberia.

MESSRS. B. ARTIS and H. L. Maxwell have estimated the amounts of barium present in the leaves of certain tobaccos and trees, and publish the results in the *Chemical News* for August 11. The barium seems to be present in the ash of the leaf, partly as sulphate and partly in a form soluble in hydrochloric acid. The tobaccos examined were grown in Cuba, Pennsylvania, Connecticut, Sumatra, Wisconsin, and Mexico. The amount of barium (calculated as sulphate) found varied from 0·0132 per cent. to 0·0980 per cent. in the leaf, the lowest amount being found in the tobacco from Mexico and the highest in that from Pennsylvania. The stems invariably contained a larger amount. In the leaves of the trees examined the amount of barium sulphate found varied from 0·0071 per cent. (Sumac) to 0·0941 per cent. (wild grape) in immature leaves. In the mature leaves the amount is generally greater than in the immature where comparison is possible.

ACCORDING to a note by Mr. A. W. Knapp in the *Chemical News* for August 18, the pink colour frequently noticed by analysts to develop on the surface of margarine fat which has been exposed in the laboratory is not due to bacterial growth or to the action of light or oxygen. It is caused by the action of the vapour of mineral acids on a dye (probably dimethylamidoazobenzene) frequently present in margarine. A method of detecting the dye is described.

A NEW system of signalling which dispenses with semaphores has been in use on a section of the Pennsylvania Railroad for nearly eighteen months, and is described in the *Engineer* for September 1. Daylight lamp signals having a range of visibility of about 2500 ft. in broad daylight had been obtained, using a lamp of not less than 20 watts and a lens 8 in. to 10 in. diameter. In 1914 Dr. Churchill, of the Corning Glass Company, discovered the possibility of securing very long range from a small lamp arranged in the exact focal centre of a small wide-angle lens. Each light unit consists of a box painted dull black on the inside, and containing a 12-volt 6-watt lamp with tungsten horizontal helical filament. The lamp is placed in the focus of a lens 5·5 in. diameter, having a focal length of 2·25 in. In front of the lens is a convex glass cover of the same diameter, and is so constructed as to avoid the difficulty of sun glare, which was at first experienced when a flatter cover-glass was used. A 4-in. spherical mirror is placed over the lamp, and is so arranged as to give the signal indication at extremely close range. A hood 11 in. long is placed over the cover-glass in order to concentrate the lamp rays and to exclude the sun's rays. The article contains clear illustrations of the arrangement.

WE are informed that Messrs. Macmillan and Co., Ltd., have become the sole agents for the sale at home and abroad of the publications of Messrs. W. and A. K. Johnston, Ltd., of Edinburgh.

## OUR ASTRONOMICAL COLUMN.

MAXIMA OF MIRA CETI, 1915.—From observations made between November 21, 1914, and March 8, 1916, Mr. Felix de Roy has concluded that the dates of maxima of Mira Ceti were January 25, 1915 (mag. 3·8), and December 20, 1915 (mag. 3·0), while the intervening minimum (mag. 8·7) occurred on August 22 (*Mem. della Soc. degli Spett. Ital.*, vol. v., series 2, July). The first maximum of 1915 was the feeblest observed since 1896, and its abnormal character has already been discussed by A. Bemporad (NATURE, vol. xcv., p. 405). The brightness at the minimum was also exceptional, having been equalled or exceeded only at six of the forty-three minima which have been sufficiently recorded. The second maximum of 1915 showed a normal amplitude of variation, and a normal interval from minimum to maximum, and a return of the star to normal conditions is suggested. A general discussion of the "perturbations" indicates the probability that the diminution and re-establishment of the brightness at maximum, of the amplitude, and of the interval from maximum to minimum, are progressive, and pass through a minimum when the maximum is abnormal. The disturbances usually extend through

Digitized by Google

three or four periods, but the three elements are not always simultaneously affected, and no periodicity for the abnormal maxima can yet be established.

A FAINT STAR WITH LARGE PROPER MOTION.—The greatest proper motion yet known for any star has been discovered by Prof. Barnard from a comparison of photographs taken with the 10-in. Bruce telescope, with the aid of the Zeiss blink-microscope. The star in question is one of the 11th magnitude, situated in R.A. 17h. 53m. 44s., declination +4° 27·4′ (1916·0), and the annual proper motion, in a northerly direction, amounts to about 10″. The star follows B.D.+4° 3560 by 9·5s., and is 0·4′ north. The motion is confirmed by numerous plates taken at Harvard, dating from 1888 (Harvard Bulletin, 613). The greatest proper motion previously known was that of Cordoba zones, 5h. 243, magnitude 8·3, R.A. 5h. 8m., declination −45°, amounting to 8·7″ per annum. The well-known star, 1830 Groombridge, of magnitude 6·5, comes next with a proper motion of 7″ per annum.

THE VAN VLECK OBSERVATORY.—The Van Vleck Observatory of Wesleyan University at Middletown, Connecticut, was dedicated on June 16. The observatory is the gift of the late Joseph Van Vleck, in commemoration of the services rendered to the University by his late brother, John Monroe Van Vleck, who had been professor of mathematics and astronomy for many years. The chief instrument is an equatorial refracting telescope of 18½-in. aperture and 26 ft. focal length, but the completion of the objective has been delayed by the war, and a 12-in. lens is temporarily in use. The observatory is designed for purposes of instruction and research, and, in addition to the large telescope, is provided with two small transits and numerous portable instruments. The director is Prof. F. Slocum, who is well known for his successful work at the Yerkes Observatory. It is intended to apply the large telescope chiefly to the photographic determination of stellar parallaxes (*Popular Astronomy*, vol. xxiv., No. 7).

THE SYSTEM OF POLARIS.—Spectroscopic observations have revealed the existence of two close companions to Polaris, one having a period of about four days, and the other of about twelve years. From a discussion of all the available data, L. Courvisier, of the Berlin-Babelsberg Observatory, has concluded that the visible 9th magnitude companion to Polaris is also a member of the system, its period of revolution being at least 20,000 years (*Astronomische Nachrichten*, 4854). The mass of Polaris itself is probably not greater than one-fourth that of the sun, and its density not more than 0·003 of the sun's density. The deduced parallax of Polaris is 0·053″. The maximum separation of the companion having a period of twelve years is given as 0·20″, and this may be reached about the beginning of next year.

## THE AMSTERDAM COLONIAL INSTITUTE.

FOR some years past a movement has been in progress in Holland having for its object the foundation of a colonial institute in Amsterdam commensurate with Dutch colonial interests, and adequately representative of the important part which Holland has taken in the prosecution of research in tropical agriculture and forestry. There has existed at Haarlem for ties have in hand a capital sum of about 1,600,000 florins, which is apparently all available for the construction of buildings and the installation of the new institute. The latter will apparently be supported mainly by subsidies from the Government, the province of North Holland, and the city of Amsterdam, and by subscriptions from private individuals and firms. In 1914 the ordinary annual expenditure was 91,600 florins, but for 1915 the estimate is 78,000 florins, certain of the subsidies having been cut down owing to war economies.

As at present organised, the institute comprises three sections: *Economic* (which is practically the Haarlem museum transferred to new quarters), *Anthropological*, and *Tropical Hygiene*. It corresponds, therefore, on a small scale to the Imperial Institute of the United Kingdom as regards technical and economic work on colonial products, and to the British Schools of Tropical Medicine as regards tropical hygiene. There is, of course, nothing in this country as yet corresponding to the anthropological section of the Amsterdam institute. A site for the new buildings has been secured on the Oosterbegraafplaats, where a building to house the administrative offices and the economic and anthropological sections will be erected with a front of about 170 yds. on the Maurits Kade and about 75 yds. on Linnaeus Straat. A special building for the section of tropical hygiene will be erected as part of the buildings of the Hygienic Institute of the University of Amsterdam, with which this section will work in close co-operation.

The institute has already issued a number of publications, perhaps the most interesting being a concise history by Dr. Sirks of research in natural science in the Dutch East Indies (Koloniaal Instituut te Amsterdam, Mededeeling, No. vi. Afdeeling Handelsmuseum, No. 2).

## LAND-SLIDES ON THE PANAMA CANAL.[1]

A COMMITTEE of the U.S. National Academy of Sciences spent the last fortnight of the year 1915 on the Canal zone studying the great land-slides of the Culebra Cut. These are three in number, and are all comprised within a mile or a little more of the Canal bank. The moving ground consists almost entirely of the stratified rocks known as the Cucuracha or Culebra beds. The East Culebra slide and the Cucuracha slide lie north and south of the core of basalt and hard tuff which forms the high central mass of Gold Hill, the flanks of which are composed of the aforesaid stratified rocks. On the west side of the Canal there are three summits of massive rock, tuff or basalt, viz. Contractor's Hill, nearly opposite to Gold Hill; Zion Hill, north of Contractor's Hill; and Culebra Hill, north of Zion Hill. The third great slide, the only one on the west bank of the Canal, known as the West Culebra slide, lies between Zion and Culebra Hills.

The committee finds that no great extension of the slides in the soft Cucuracha or Culebra beds is probable, because the rock itself is limited in extent, and because the broken ground already extends in many places beyond the crest of the slope.

It also reports upon the important question of the stability of Gold Hill, Contractor's Hill, Zion Hill, and Culebra Hill, which rise considerably above the level of the sliding ground. The confident expectation

Digitized by Google

tance, no reason is apparent why these hills should not presently share in the movement of the material which lies upon their flanks. The apprehension is all the more natural because great chunks of the massive rock have broken from the parent masses adjacent to the sliding ground. When, however, we examine the materials closely we find a great difference in character between the central, and highest, part of these hills and the lower slopes which slide. The committee reports that the hills consist of intrusive bodies of basalt or of masses of hard Obispo tuff, and that, so far as the exposures show, they do not rest upon the soft beds, but extend far down below Canal bottom. The committee is therefore of opinion that although rock may break off from them, they will not collapse.

In this connection it is important to note the observation in the report that there has been no upheaval of the Canal bottom between Gold Hill on the east, and Contractor's Hill, nearly opposite to it, on the west, side of the Canal, which is the deepest part of the cut. This shows that the hills are not pressing on the bottom.

Thus the findings of the committee, and the evidence in their report, favour the opinion that the establishment of a permanent waterway free from interruption is only a question of time; of time to be reckoned, not in months, indeed, on one hand, but certainly not in centuries on the other. It thinks that "some sliding ground will continue to enter the Canal for several years to come," and it recommends that certain steps be taken to lessen its amount. These recommendations have to do with the control of the rain-water, which in this region of great precipitation adds so much to the weight of porous, stratified rocks, and so greatly diminishes their cohesion. The committee proposes, therefore, that the growth of vegetation should be promoted, that cracks should be filled up as soon as formed, that surface and tile drainage should be undertaken in threatened areas, and that drains should be established on the moving ground of the three great slides. VAUGHAN CORNISH.

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

IT is announced in the issue of *Science* for August 18 that Lafayette College is the residuary legatee of the late Mr. A. N. Seip, of Washington, D.C. It is said that the college will ultimately receive not less than 50,000*l*.

THE Elgar Scholarship of the Institution of Naval Architects, of the annual value of 100*l*., and, subject to certain regulations, tenable for three years, has been awarded to Mr. R. J. Shepherd, of his Majesty's Dockyard, Devonport.

IT is stated in a recent issue of *Science* that the vocational-educational Bill, providing for Federal co-operation with the various States in promoting agricultural and industrial education in the United States, makes an annual appropriation beginning at 100,000*l*. and increasing each year by 50,000*l*. until 600,000*l*. is reached, to be apportioned to the States in proportion to their rural population.

THE calendar for 1916–17 of the Edinburgh and concurrent. The calendar contains full details of the courses of instruction available in the departments of agriculture, horticulture, and forestry. The aim of the college is to supply such training in agriculture and the sciences underlying it as is nowadays indispensable to all who intend to gain their living from the land as owners, or tenants, or agents. Copies of the calendar may be obtained from the secretary of the college, 13 George Square, Edinburgh.

A CONFERENCE representative of the Classical, English, Geographical, Historical, and Modern Language Associations has drawn up the following resolutions, which have received the approval of the councils of the five associations named:—That in the opinion of the conference: (1) It is essential that any reorganisation of our educational system should make adequate provision for both humanistic and scientific studies. (2) Premature specialisation on any one particular group of studies, whether humanistic or scientific, to the exclusion of all others, is a serious danger, not only to education generally, but to the studies concerned. (3) Humanistic education implies the adequate study of language and literature, geography and history, which in each case should, at the appropriate stages of education, go beyond the pupils' own language and country. (4) The representatives of humanistic studies would welcome from the representatives of the mathematical and natural sciences a statement with regard to those studies similar to that contained in (3). (5) In all reform of education it must never be forgotten that the first object is the training of human beings in mind and character, as citizens of a free country, and that any technical preparation of boys and girls for a particular profession, occupation, or work must be consistent with this principle. (6) Subject to the above principles the associations concerned would welcome a comprehensive revision of national education from the point of view of present needs. It is stated that "the resolutions are published in the hope that in any coming reconstructions of our educational system this attempt to restate the 'humanistic' position will mitigate the dangers incident to a violent breach of tradition and an excessive reaction against the past predominance of certain types of study. But it will be obvious that they are drawn up in no spirit of hostility or indifference to either scientific or technical studies, and their framers are anxious to co-operate in securing for these, as well as for the studies with which they are themselves more particularly interested, their due place in a national system of education." Co-operation and suggestions are invited; any communication may be addressed to the chairman of the Conference of the Five Associations, Prof. T. F. Tout, Oak Drive, Fallowfield, Manchester.

## SOCIETIES AND ACADEMIES.

### PARIS.

**Academy of Sciences**, August 21.—M. Paul Appell in the chair.—A. **Lacroix**: Some volcanic rocks of the French possessions in the Indian Ocean and the Pacific.—Paul **Appell**: The developments of the square root of a polynomial in continued fractions.—W. H. **Young**: The convergence of Fourier's series.—M.

Digitized by Google

of the planets.—H. **Bordier**: The action of light on dilute aqueous solutions of iodine and iodide of starch. Dilute solutions of these two substances, stable in the dark, are bleached by the action of light. The hypothesis put forward to explain this fact is based on the supposition that both iodine and iodide of starch do not form true solutions but colloidal solutions.—A. **Blanchetière**: The relations between the chemical constitution of certain derivatives of amino-acids and the mode of attack of these substances by bacteria.—Ch. **Dhéré** and G. **Vegezzi**: The influence exercised by the degree of reduction of the hæmochromogens on their spectra.

NEW SOUTH WALES.

**Linnean Society**, June 28.—Mr. C. Hedley, vice-president, in the chair.—R. J. **Tillyard**: Studies in Australian Neuroptera. No. iii., The wing-venation of the Chrysopidæ. The paper shows the method adopted in extracting the pupa of Chrysopa from its cocoon, and preparing the wing-sheaths for photomicrography. The result of a study of the pupal wing tracheation demonstrates that the Chrysopidæ are the most highly specialised of all Neuroptera. In the hindwing the point usually taken as the origin of Rs is shown to be a false origin, the true basal portion being fused with M. In both wings the veins usually named the media and cubitus are shown to be highly complex formations developed from consecutive, short portions of the true media, true cubitus, and the more proximal branches of the radial sector. These latter are termed the Banksian sectors, since their part in the above formations is similar to that of the branches forming the Banksian line in Myrmeleontidæ. The two composite veins themselves are named the pseudomedia (L′) and pseudocubitus (Cu′) respectively. No corresponding veins are known anywhere else in the class Insecta. The true media is shown to be branched in both wings, Banks's "divisory veinlet" in the forewing being formed by divergence and distal re-fusion between $M_2$ and $M_1$. The paper concludes with a phylogenetic discussion in which the venation of the Apochrysidæ is compared with that of the Chrysopidæ, and the descent of these families from an original Osmylid-like stock, *vid* forms like the Jurassic Mesochrysopa, is indicated.—Dr. A. J. **Turner**: A third contribution to a knowledge of the Lepidopterous fauna of Ebor Scrub, N.S.W. Four additional visits to the Scrub, in January, 1916, resulted in 128 captures, representing forty species, twenty-two of which have been previously recorded. Six of the remaining eighteen are known to occur elsewhere, and twelve are now described as new, as well as an interesting geometrid obtained in 1914, but overlooked. The number of recognised species amounts to sixty-nine, of which only twenty-four are known from other localities.—M. **Aurousseau**: Petrological notes. No. ii., The relations between some West Australian gneissic and granitic rocks. The observations recorded are grouped under two heads—"The Geology of the Roelands District," and "The Crystalline Rocks of Albany."

## LONDON COUNTY COUNCIL.

**EVENING CLASSES** in Science and Mathematics are held at the undermentioned institutions maintained by the London County Council :—

BEAUFOY INSTITUTE, Princes Road, Vauxhall Street, S.E. (Mathematics and Elementary Science.)

HACKNEY INSTITUTE, Dalston Lane, N.E. (Mathematics, Chemistry, Physics.)

NORWOOD TECHNICAL INSTITUTE, Knight's Hill, West Norwood, S.E. (Mathematics, Chemistry, Physics, Botany.)

PADDINGTON TECHNICAL INSTITUTE, Saltram Crescent, W. (Mathematics, Physics, Chemistry, Botany.)

Full Prospectuses may be obtained on application to the Secretaries of the respective institutions.

JAMES BIRD,
*Clerk of the London County Council.*

London County Council Education Offices, Victoria Embankment, W.C., September, 1916.

## UNIVERSITY OF BIRMINGHAM.

ASSISTANT LECTURESHIP IN MATHEMATICS.

The Council invites applications for the post of Assistant Lecturer in Mathematics (Man or Woman). Stipend £175 per annum. Applications, accompanied by three or four testimonials, should be sent to the undersigned not later than Monday, September 18, 1916. The Candidate elected will be required to enter upon the duties on October 3, 1916.

Further particulars may be obtained from

GEO. H. MORLEY, Secretary.

## NORTHAMPTON POLYTECHNIC INSTITUTE, LONDON, E.C.

TECHNICAL OPTICS DEPARTMENT.

Applications are invited for the full-time post of DEMONSTRATOR in the OPTICAL LABORATORIES. The salary will depend upon qualifications and experience. For particulars and application forms apply to

R. MULLINEUX WALMSLEY, D.Sc.,
Principal.

## FOR SALE.—About a thousand Right-Angle

Prisms 36 × 16 × 18 m/m., in which are defects such as dead metal, bubbles, &c., rendering them unsuitable for Pri-m Binoculars. Useful for demonstration purposes. Glass alone cost about 2s. Price 9d. each. —WATSON & SONS, 313 High Holborn, W.C.

## STEVENS' AUCTION ROOMS. Estd. 1760.

FRIDAY, SEPTEMBER 15TH, AT 12.30 O'CLOCK.

## MR. J. C. STEVENS has received instruc-

tions from the Executors of the late Rev. W. T. KINGSLEY, to Sell by Auction the whole of the Scientific Apparatus, including a Binocular Microscope by Ross, with a variety of Objectives and Slides, also the well-made Cabinet in which the slides are contained; an 8-day Ship's Chronometer; 4½-inch Astronomical Telescope with Eyepieces and Altazimuth Movement; 3½-inch Telescope by Ross, with Equatorial mount by Cooke & Son, an expensive Sidereal Clock by Dent; Micrometer, Solar Mirrors; Lathe, Stereoscope, Optical Lantern, and a variety of very useful Apparatus.

On view day prior from 12.30 till 5.30, and morning of sale from 9.30 till 12 Catalogues on application to 38 King Street, Covent Garden, London, W.C.

## MARINE BIOLOGICAL ASSOCIATION OF THE UNITED KINGDOM.

THE LABORATORY, PLYMOUTH.

**The following animals can always be supplied, either living or preserved by the best methods :—**

Sycon; Clava, Obelia, Sertularia; Actinia, Tealia, Caryophyllia, Alcyonium; Hormiphora (preserved); Leptoplana; Lineus, Amphiporus, Nereis, Aphrodite, Arenicola, Lanice, Terebella; Lepas, Balanus, Gammarus Ligia Mysis, Nebalia, Carcinus; Patella, Buccinum, Eledone, Pectens Bugula, Crisia, Pedicellina, Holothuria, Asterias, Echinus, Sulpa (preserved), Scyllium, Raia, &c., &c.

## HARLING'S NEW "ACRIBO" SECTIONAL PADS

COMBINE

**ABSOLUTE ACCURACY—GOOD PAPER—LOW PRICE**

Printed in grey, ensuring visual comfort, and allowing plotted matter to show up well in any colour.

No. 1 : inches and 8ths. No. 2 : inches and 10ths.
No. 3 : centimetres and millimetres.

Price of either, 50 sheets in a pad with cover, **2/6.**

☞ NATURE says : "The paper is excellent, the ruling is accurate, the pad is convenient, and the production is British throughout."

*Write for specimens (post free) and compare the accuracy with any you have in use.*

## JUST PUBLISHED.

***The very book for these troublous times.***

## A MODERN JOB: An Essay on the Problem of Evil.

By ETIENNE GIRAN. Translated by FRED ROTHWELL. With a Portrait of the Author and an Introduction by ARCHDEACON LILLEY. 92 pages. Cloth, 2*s.* 6*d.* net. Postage 3*d.* extra.

**The book is alive,** and the ideas propounded seem actually to have become incarnate in Eliphaz. Bildad, and Zophar. The author gives these ideas a voice, which speaks in words of utmost sincerity and passionate feeling. The reader is irresistibly attracted by the strong and noble eloquence of a thinker whose simple style and intense loyalty to truth should prove a rare stimulus to **lofty endeavour and devoted purpose in these troublous times.**

## THE CONTINGENCY OF THE LAWS OF NATURE.

By EMILE BOUTROUX, of the French Academy. Translated by FRED ROTHWELL. With a Portrait of the Author. Pages x, 196. Cloth, 5*s.* net. Postage 4*d.* extra.

The two leading ideas of this work are, first, that philosophy should not confine itself to recombining eternally the concepts handed down by our forerunners, but rather should come into direct contact with the realities of nature and science; and, secondly, that philosophical systems, whether idealistic, materialistic, or dualistic, regard the laws of nature as necessary, and, consequently, that they are destructive of true life and freedom. A natural law is not a first principle, it is a result; and life, feeling, and liberty are realities whereof the comparatively rigid forms grasped by science are the ever inadequate manifestations. Men can act on nature because nature is neither brute force nor lifeless thought. The laws of nature, if necessary, would typify the rigidity and immobility of death. Being contingent, they give more dignity to life, a greater incentive to rise in the scale of being.

## GEORGE BOOLE'S COLLECTED LOGICAL WORKS.

In two volumes, of which the second, containing the *Laws of Thought*, is ready. Pages xvi, 448. Cloth, 15*s.* net per volume. Postage 5*d.* extra.

The second volume contains a reprint of the *Laws of Thought* of 1854, unaltered, except that misprints are of course corrected. Both volumes are provided with indexes, and the page-numbers of the original publications are throughout inserted in square brackets and heavy type at the proper places.

*In the catalogue and supplements (post free) are descriptions of other new books that will interest you.*

# SUCCESS !

If success in your experiment is dependent upon the Filter Paper; it may be commanded by the use of Whatman Filter Paper.

**For all general filter purposes use Nos. 1-5. There are at present Four Acid Extracted grades (practically ashless), two more, Nos. 43 and 44, are in preparation.**

## WHATMAN FILTER PAPER

**No. 1.** **Equivalent to C.S. & S. 595.**

**No. 2.** **Equivalent to C.S. & S. 597.**

**No. 3.** **Equivalent to C.S. & S. 598.**

**No. 4.** **Equivalent to C.S. & S. 604.**

**No. 5.** **Equivalent to C.S. & S. 602.**

**No. 30.** Hydrochloric acid treated. Low ash, close texture. For quantitative work. **Equivalent to DREVER-HOFF 207.**

**No. 40.** A paper treated by both Hydrochloric and Hydrofluoric acids. Has less ash than No. 30. For very accurate quantitative work. Retains finest precipitates. **Equivalent to C.S. & S. 589.** (White Ribbon.)

**No. 41.** Treated same as No. 40, but more open and filters more quickly. Not recommended for filtering very fine precipitates unless properly precipitated. **Equivalent to C.S. & S. 589.** (Black Ribbon.)

**No. 42.** A new grade, resembling Nos. 40 and 41 in chemical qualities, but differing in its physical properties, being much harder and extremely close in texture. Suitable for use in filter pumps. **Equivalent to C.S. & S. 589.** (Blue Ribbon.)

**Nos. 43 and 50, also Folded Filters and Fat Extraction Thimbles will be out shortly.**

# THE SIR JOHN CASS TECHNICAL INSTITUTE,

JEWRY STREET, ALDGATE, E.C.

The following Special Courses of Instruction will be given during the Autumn Term, 1916:—

## THE THEORY AND APPLICATIONS OF MATHEMATICAL STATISTICS.

By E. C. SNOW, M.A., D.Sc.

A course of 10 lectures on the modern mathematical methods of dealing with statistical data in social, educational, economic and medical problems, suitable to teachers and students of economics. Opportunity will be given to students to take up problems on their own account, and assistance and direction will be given for such work.

**Wednesdays, from 5.30 to 6.30 p.m.**

The first lecture of the course will be given on Wednesday, October 4, 1916.

## THE METHODS OF DIFFERENTIAL AND INTEGRAL CALCULUS AND THEIR APPLICATION TO CHEMICAL AND PHYSICAL PROBLEMS.

By R. S. WILLOWS, M.A., D.Sc.

A course of 10 lectures for those engaged in Chemical and Electrical Industries and students of Physical Chemistry, in which the subject will be treated more as a means of Chemical and Physical investigation, rather than from the mathematician's standpoint.

The standard of mathematics required on joining the class will not go beyond an elementary knowledge of Algebra.

**Friday evenings, 7 to 8 p.m.**

The first lecture of the course will be given on Friday, October 6, 1916.

Detailed syllabus of the courses may be had upon application at the Office of the Institute, or by letter to the PRINCIPAL.

EVENING CLASSES IN CHEMISTRY, PHYSICS and MATHEMATICS designed to meet the requirements of those engaged in Chemical and Electrical Industries and in trades associated therewith.

The Institute contains well-equipped laboratories in which every facility is provided for

**Advanced Practical Work and Research**

both in the afternoon and evening.

A full curriculum for the B.Sc. examination of London University in Physics, Chemistry and Mathematics is provided under recognised teachers of the University.

**New Session begins Monday, September 25th.**

For details of the courses apply at the Office of the Institute or by letter to the PRINCIPAL.

UNIVERSITY OF LONDON.

# KING'S COLLEGE, AND KING'S COLLEGE FOR WOMEN.

FACULTY OF SCIENCE.

In this Faculty a Course of Study in Science is provided suitable for general education or for the Examinations of the London and other Universities.

Students are admitted either as Regular or Occasional Students. Several valuable Scholarships and Prizes are offered.

The Laboratories of the College are open to post-Graduates and Research Students.

The following are the Departments under the charge of the various Professors, assisted by the Junior Staff:—

| | |
|---|---|
| Mathematics ... ... | Prof. S. A. F. WHITE, M.A.<br>Prof. J. W. NICHOLSON, M.A., D.Sc. |
| Physics ... ... ... | Prof. O. W. RICHARDSON, D.Sc., F.R.S. |
| Chemistry ... ... | Prof. H. JACKSON, F.I.C., F.C.S.<br>Prof. A. W. CROSSLEY, D.Sc., F.R.S. |
| Botany ... ... ... | Prof. W. B. BOTTOMLEY, Ph.D., F.L.S. |
| Zoology ... ... ... | Prof. ARTHUR DENDY, D.Sc., F.R.S. |
| Geology and Mineralogy | Dr. W. T. GORDON, F.R.S.E. |
| Physiology ... ... | Prof. W. D. HALLIBURTON, M.D., LL.D., F.R.S. |
| Psychology ... ... | Dr. W. BROWN, M.A., M.B. |

The next TERM begins WEDNESDAY, OCTOBER 4, 1916.

For particulars as to this and other Faculties of the College—Engineering, Medicine, Arts, Laws, and Theology—apply to the SECRETARY, King's College, Strand, W.C.

THE MANCHESTER MUNICIPAL

# SCHOOL OF TECHNOLOGY

## (UNIVERSITY OF MANCHESTER).

PRINCIPAL: J. C. M. GARNETT, M.A. (late Fellow of Trinity College, Cambridge).

The Prospectus, forwarded free on application, gives particulars of the courses leading to the Manchester University degrees in the Faculty of Technology, in the following departments:—

MECHANICAL ENGINEERING,
ELECTRICAL ENGINEERING,
SANITARY ENGINEERING (including Municipal Engineering),
THE CHEMICAL INDUSTRIES (including General Chemical Technology, Bleaching, Dyeing, Printing, Papermaking, Brewing, and Metallurgy),
THE TEXTILE INDUSTRIES,
PRINTING AND PHOTOGRAPHIC TECHNOLOGY,
MINING,
ARCHITECTURE.

During the Session 1916-1917, First Year Courses will be specially adapted to the requirements of students who may wish to take Commissions in H.M. Forces.

ENGINEERING AND TECHNICAL OPTICS.

# NORTHAMPTON POLYTECHNIC INSTITUTE,

ST. JOHN STREET, LONDON, E.C.

**ENGINEERING DAY COLLEGE.**

Full Day Courses in the Theory and Practice of Civil, Mechanical, and Electrical Engineering will commence on Monday, October 2, 1916. The Courses in Civil and Mechanical Engineering include specialisation in Automobile and Aeronautical Engineering, and those in Electrical Engineering include specialisation in Radio-Telegraphy.

*Entrance Examination* on Tuesday and Wednesday, September 26 and 27, 1916. These courses include periods spent in commercial workshops, and extend over four years. They also prepare for the Degree of B.Sc. in Engineering at the University of London. Fees £15 or £11 per annum.

*Three Entrance Scholarships* of the value of £52 each will be offered for competition at the Entrance Examination in September, 1916.

**TECHNICAL OPTICS.**

Full and Part Time Courses in all branches of this important department of Applied Science will be given in specially equipped laboratories and lecture rooms. *An Aitchison Scholarship* (value £30) will be offered in this department at the Entrance Examination.

Full particulars as to fees, dates, &c., and all information respecting the work of the Institute, can be obtained at the Institute or on application to

R. MULLINEUX WALMSLEY, D.Sc., Principal.

# EDINBURGH & EAST OF SCOTLAND COLLEGE OF AGRICULTURE.

SESSION 1916-17.

The WINTER SESSION begins on TUESDAY, OCTOBER 10.

The DAY CLASSES, in conjunction with certain University Classes, provide full courses of instruction in Agriculture, Horticulture, and Forestry.

Full particulars of Courses and Classes, and also of Bursaries tenable at the College, are given in the Calendar, copies of which may be obtained on application.

All the College Courses are open to Women Students.

ALEXANDER M'CALLUM, M.A., LL.B.,
Director and Secretary.

## THE UNIVERSITY OF SHEFFIELD.

OPENING OF SESSION 1916–17.

The Session OPENS as follows:—

DAY CLASSES.

| | | |
|---|---|---|
| FACULTY OF APPLIED SCIENCE | ... | September 25 |
| FACULTY OF ARTS | ... | October 4 |
| FACULTY OF PURE SCIENCE | ... | October 4 |
| FACULTY OF MEDICINE | ... | October 4 |
| FACULTY OF LAW | ... | October 4 |
| DEPARTMENT OF ARCHITECTURE | ... | October 4 |

EVENING CLASSES.

| | | |
|---|---|---|
| FACULTY OF APPLIED SCIENCE | ... | September 25 |
| FACULTY OF ARTS | ... | October 9 |
| FACULTY OF PURE SCIENCE | ... | October 9 |
| FACULTY OF LAW | ... | October 9 |
| DEPARTMENT OF ARCHITECTURE | .. | October 9 |

Prospectuses may be had free on application.

W. M. GIBBONS, Registrar.

## THE UNIVERSITY OF SHEFFIELD.

EDGAR ALLEN SCHOLARSHIPS

The following ENTRANCE SCHOLARSHIPS, each of the value of £100 per annum, and tenable for three years, are offered:—

(*a*) TWO SCHOLARSHIPS, open to men and women who will not have completed their 20th year at the beginning of the University Session in which they enter the University.

(*b*) TWO SCHOLARSHIPS, restricted to the "sons of workmen earning daily or weekly wages and foremen of workmen and managers."

An examination for the above Scholarships will be held in December next, and entries must be sent to the REGISTRAR by October 31.

Full particulars of these Scholarships may be obtained free from

W. M. GIBBONS, Registrar.

## THE UNIVERSITY OF SHEFFIELD.

COURSES are held and DEGREES are awarded in the following Faculties: ARTS (including Architecture), PURE SCIENCE, MEDICINE, LAW, APPLIED SCIENCE (including Engineering, Metallurgy, Mining, and Glass Technology).

The SESSION 1916–17 commences OCTOBER 4, 1916.

Entrance and Post-Graduate Scholarships are awarded each year.

Prospectuses, giving full information, may be obtained from

W. M. GIBBONS, Registrar.

LONDON, E.C.

TECHNICAL OPTICS DEPARTMENT.

Applications are invited for the full-time post of DEMONSTRATOR in the OPTICAL LABORATORIES. The salary will depend upon qualifications and experience. For particulars and application forms apply to

R. MULLINEUX WALMSLEY, D.Sc.,
Principal.

## THE UNIVERSITY OF SHEFFIELD.

DEPARTMENT OF GEOGRAPHY.

A TEMPORARY LECTURER is required in the Department of Geography for the Session 1916–17, in the absence of the Lecturer on War Service. Salary £200. The appointment is open to a man, ineligible for war service, or to a woman. Further particulars may be obtained from the undersigned.

W. M. GIBBONS, Registrar.

APPLICATIONS are invited for the temporary post of ASSISTANT in BOTANY in University College, Reading, rendered vacant by the absence on war service of Mr. R. C. McLean, Lecturer in Botany. Further particulars may be obtained from the REGISTRAR

## THE ROYAL TECHNICAL COLLEGE, GLASGOW.

SESSION 1916–17 BEGINS ON SEPTEMBER 26.

The Diploma of the College is granted in the following Departments:—Civil Engineering, Mechanical Engineering, Electrical Engineering, Mining, Naval Architecture, Chemistry, Metallurgy, Building, Textile Manufacture, Dyeing, and Sugar Manufacture. A Course for a Joint Diploma in Architecture has been arranged in conjunction with the Glasgow School of Art.

The Diploma Course extends over either three or four Sessions, and the average fee per Session is £12 12s.

The College is affiliated to the University of Glasgow, and the Degrees of the University in Engineering and Applied Chemistry are open to its students.

Full Courses of Instruction are also provided in the Schools of Navigation, Wireless Telegraphy, and Bakery.

The Calendar (price 1s., by post 1s. 4d.) and Prospectuses (free) will be sent on application to the DIRECTOR.

## A SYSTEM OF PHYSICAL CHEMISTRY.

*A System of Physical Chemistry.* By Prof. W. C. McC. Lewis. Two vols. Vol. i., pp. xiv + 523. Vol. ii., pp. vii + 552. (London: Longmans, Green and Co., 1916.) 9s. net each vol.

PHYSICAL chemistry in the present-day sense of the term may be said to date from 1887, the year in which Ramsay came to London, Ostwald was appointed to the chair in Leipzig, and the *Zeitschrift für physikalische Chemie* was founded by Ostwald and van't Hoff. Although many pioneers, amongst whom may be mentioned Deville, Debray, Guldberg and Waage, Gibbs, Horstmann, Berthelot, Thomson, Harcourt and Esson, Gladstone, Le Chatelier, and Lemoine had prepared the way for the new development in chemical science, it was the combined influence of van't Hoff, Arrhenius, Ostwald, and Ramsay that gave direction and strength to the new current of thought and research.

It is a remarkable fact that during this period of nearly thirty years the English-speaking peoples of the world have had to depend chiefly on works written in German, or their translations into English, for the accepted standard treatises on the subject. The "Lehrbuch" of Ostwald, the "Theoretische Chemie" of Nernst, and the "Vorlesungen" of van't Hoff were for many years without a serious competitor. A change in this state of affairs was brought about by the appearance of the excellent series of "Text-books of Physical Chemistry" edited by Sir William Ramsay. But as these were mostly in the nature of special treatises on different branches of the subject, the student desirous of obtaining a compact and rounded, and at the same time fairly comprehensive, view of physical chemistry as a whole had still to have recourse to the works previously mentioned. Yet none of these was entirely satisfactory. Ostwald's "Lehrbuch," though unexcelled in its historical treatment of the subject, was too cumbrous, was marred by its author's unfortunate attempt to "energeticise" thermodynamics, and has not been kept up to date. Nernst's otherwise excellent treatise repelled the student by its opening chapters, which presented the subject of thermodynamics in a Helmholtzian form unfamiliar to English students, but so generalised, so condensed, and so careless in reasoning that few students could separate the gold from the dross. Finally, the lectures of van't Hoff, though the work of a master-hand, scarcely covered the required field of study in a sufficiently comprehensive manner.

The present work, which appears as the latest volume of Sir William Ramsay's series of text-books, differs radically from its predecessors inasmuch as it essays to present the reader with a fairly comprehensive "System of Physical Chemistry." In this respect it is worthy of especial consideration and attention. It may be said at once that in its arrangement of matter, lucidity of style, and comprehensive unity of design it is destined to become the standard general treatise on the subject of physical chemistry for English-speaking students.

The frontispiece consists of a table indicating a "philosophical" classification of the subject. This is very interesting, and will be of great service in giving the student a reasoned survey of the field to be traversed. The main division is into systems in equilibrium and systems not in equilibrium. The subdivision of these is based partly on the nature of the subject-matter and partly on the method of treating it. This want of uniformity in the system of classification is, however, no defect, as it corresponds to the natural development of science. The author is to be congratulated on this emphasising of the philosophical aspect of his subject, an aspect which is all too frequently ignored by the authors of scientific treatises. For practical purposes the work is divided into two volumes. Vol. i. deals with the subject from the classical kinetic-molecular point of view. Vol. ii. is divided into two parts, part i. being entitled "Considerations based upon Thermodynamics," and part ii. "Considerations based upon Thermodynamics and Statistical Mechanics."

This method of division has a philosophical and historical as well as a practical didactic basis. As Perrin has pointed out in the beautiful preface to "Les Atomes," there are two methods by means of which the human mind advances in its understanding of the external world. In one case "on généralise des résultats d'expérience, mais les raisonnements ou les énoncés ne font intervenir que des objets qui peuvent être observés ou des expériences qui peuvent être faites." This is essentially the method of the "classical" thermodynamics, on which so much of the science of physical chemistry is based. But there is also another method—"deviner l'existence ou les propriétés d'objets qui sont encore au delà de notre connaissance, *expliquer du visible compliqué par de l'invisible simple*, voilà la forme d'intelligence intuitive à laquelle, grâce à des hommes tels que Dalton ou Boltzmann, nous devons l'Atomistique." It is to this that we owe not only the beginnings of chemical science, but also the latest advances. The trend of modern physical chemistry is largely in the direction of "Atomistique."

The author's presentation of the subject has also an important didactic advantage. Students invariably find chemical thermodynamics difficult, but read with comparative ease an exposition based on a simple kinetic-molecular method of treatment. In vol. i. they will find the latter, enlivened and brought up to date by an account of the work of Einstein, Perrin, and Svedberg on "molecular reality," and a discussion of the electron theory of matter, the structure of the atom, and the transmutation of the elements. Part i. of vol. ii. contains a good account of the thermodynamical treatment of chemical problems, includ-

Digitized by Google

ing the application of thermodynamics to electrochemistry, and the "Nernst Theorem." In part ii. the author discusses photo-chemistry, the theory of radiation, and the application of the theory of Quanta to the problems of photochemistry, radiation, and the kinetic theory of matter. These highly important aspects of what one might term the "newer physical chemistry" are dealt with in a very simple and clear fashion, and this part of the book will be exceedingly valuable to students of chemistry.

During the last decade the scope and importance of physical chemistry have become enormously increased. To write within moderate compass a good text-book on the subject has become a task of rapidly increasing difficulty. Nevertheless Prof. Lewis has achieved this task with an admirable success. One might say of him, "Jeunesse savait, jeunesse pouvait."

F. G. DONNAN.

## THE FLORA OF ALL AFRICA.

*The Flowering Plants of Africa: An Analytical Key to the Genera of African Phanerogams.* By F. Thonner. Pp. xvi+647. (London: Dulau and Co., Ltd., 1915.) Price 15*s*. net.

THE work under notice is a translation of the author's "Die Blütenpflanzen Afrikas," which appeared in 1908. The preface is dated Vienna, Austria, 1913, and the work was issued by the Burleigh Press, Bristol, in 1915. Dr. A. B. Rendle revised the translation, which includes "diagnostic characters of the genera, the approximate number of African species described up to the end of the year 1910; their geographical distribution, their uses, and their more important synonyms." So far as tested, it is up to the date named; but six years' additions are very considerable, Kew alone having published at least 300 new species, leaving new genera out of the question. But comprehensive compilations necessitate supplements if they are brought as nearly as possible up to date of publication; and Thonner gives six pages of corrections and additional genera, chiefly from the years 1911 and 1912.

The descriptive part of the work occupies about 550 pages, and the general distribution of the genera enumerated is set forth in a statistical table. It should be understood that only families and genera are described, and the classification is Englerian. The area embraced includes all the African islands, from the Azores to Tristan da Cunha, and Socotra, the Mascarenes, and Madagascar to Kerguelen. And the geographical divisions of the mainland are physical rather than political. Thonner's enumeration and estimates afford a record of 226 families of flowering plants indigenous in the African region, and represented therein by 3551 genera and 39,800 species, or say 40,000. His estimate for the world is 10,055 genera, with a total of 144,500 species, and his figures are certainly not too high. The table also shows the numbers for North, Central, and South Africa, and the Malagasy Islands.

Other features of the book are: a condensed bibliography, a glossary, indexes to the popular and botanical names, and a list of the plates and the abbreviations of authors' names. The plates are excellent, and represent members of 150 families, and the letterpress is clear and idiomatic. Wherever possible the author has chosen as distinctive characters such as are visible to the naked eye in a plant in flower. First comes a key to the families, followed by descriptions of the same, and under each a key to its genera, including a considerable number of introduced plants. The plan and scope of the work have been somewhat fully explained, because that seemed a more useful course than a technical criticism. Its full value can only be determined by actual use; but an elementary knowledge of external morphology and descriptive terminology would be necessary and sufficient to enable the student to understand the treatment of the subject. As a book of reference only it answers many interesting questions.

W. BOTTING HEMSLEY.

## CHRISTIANITY IN PARTIBUS.

*The Nestorian Monument in China.* By Prof. P. Y. Saeki. Pp. x+342. (London: Society for Promoting Christian Knowledge, 1916.) Price 10*s*. 6*d*. net.

THIS volume deals with one of the most interesting romances of literature ever known. The story has often been told before; but it will bear repetition, on the chance of reaching some whose reading may have lain in other directions.

The Christian religion, under the guise of what is now known as the Nestorian heresy, was carried to China early in the seventh century A.D. by a mission dispatched under the auspices of adherents who had been for some time seeking in the Far East the development which was denied to them in the West. Nestorius had been appointed Patriarch of Constantinople in A.D. 428, but in an evil moment for himself he conceived the idea that all difficulties as to Christ's birth would vanish if it were understood that He had distinct human and divine persons. For this he was deposed in 431, and a few years later he disappeared.

Nestorianism survived its founder for many centuries. Reaching China in the year 631, its advance was so rapid that by 635 Nestorian missionaries were allowed to settle at the capital, where for a couple of centuries they enjoyed Imperial protection and even patronage. In 781 the Nestorian Church of the day set up a huge stone tablet, more than 9 ft. in height, more than 3 ft. in breadth, and about a foot thick. On this tablet an inscription was carved, in Chinese and Syriac, explaining and glorifying the Christian religion, and celebrating the praises of the great and good Emperors who had permitted this teaching to take root and flourish. For flourish it unmistakably did, and so it was found in the thirteenth century by Marco Polo. Then, during the fourteenth century, it faded away, leaving no

Digitized by Google

trace of any kind that it had ever existed. There is no mention of Nestorianism in the Chinese dynastic histories; no mention of it in any of the contemporary or later Chinese authors whose writings have covered every department of literature. Nor should we now know anything of the early advent of Christianity in China but for an extraordinary accident. In 1625 it came to the notice of Catholic missionaries that the tablet above described, and of which all knowledge had long been lost, had been unearthed somewhere near the old capital, at which we now know from the tablet that Christianity had flourished as above stated. The tablet was denounced as a Jesuit forgery by Voltaire and others, but for a long time there has not been the slightest doubt of its genuineness, and this point is somewhat laboured by Prof. Saeki, who thinks that it "has been preserved by the Divine Providence to reveal to us the true condition of the spiritual side" of China between A.D. 618 and 907.

Prof. Saeki's work is divided into three parts. The first part gives a general history of Nestorianism, especially in relation to the Far East, and the full story of the tablet, not omitting the attempt of Mr. Frits Holm in 1907 to carry it away to America. This enterprising traveller had to be content with a replica, now in the Metropolitan Museum, New York. Prof. Saeki mentions a second replica, "which stands to-day at the top of Mt. Koyd, the Holy Land of Japan," where, we are told, "it was dedicated, with full Buddhist ceremonial, on Sunday, October 3, 1911."

The second part of the book—the translation of the inscription—is the least satisfactory, though it is just there that improvement would be most welcome. A single example must suffice. In the description of the Messiah we read (p. 164): "Hanging up the bright Sun, He swept away the abodes of darkness." This, of course, is unintelligible. The Chinese text means, "He *was* hung up, a bright sun, in order to prevail against the gates of hell"—a light to "lighten our darkness," alluding to the Crucifixion.

The notes on the text which form the third part are interesting and in many cases valuable.

## OUR BOOKSHELF.

*Preservatives and Other Chemicals in Foods: Their Use and Abuse.* By Prof. Otto Folin. Pp. 60. (Cambridge: Mass. Harvard University Press. London: Oxford University Press, 1914.) Price 2*s.* 6*d.* net.

PROF. FOLIN'S lecture is a judicious and temperately expressed statement of the arguments for and against the use of preservatives in foods, but it adds little or nothing to our knowledge, and will scarcely tend towards forming a sound public opinion. He who seeks for an *ex cathedra* statement whether the addition of "chemicals" should be permitted to food at all, and if so, what alone should be tolerated, will find nothing in the way of definite pronouncement and not much in the way of light or leading. The author apparently halts between two opinions. He is constrained to admit that modern conditions of food supply would seem to require the use of such substances. They have been forced upon the community as a commercial necessity, and the consumer is powerless to resist.

The uncertain attitude of the author, however disappointing it may be to his readers, is at least intelligible. The fact is, no one is in a position to dogmatise on the subject, for as regards certain of the chemical products which are capable of retarding or preventing the decomposition of alimentary substances we have no positive knowledge concerning their action on the economy. Nor is it easy to obtain this knowledge. The usual argument that if they retard or prevent the action of the enzymes or bacteria which are concerned in the decomposition or decay of food they will equally inhibit the action of those agencies in effecting its digestion, begs the question and is unsound. Age, idiosyncrasy, condition of health, and a number of other circumstances affect the matter: what is toxic to one person is harmless to another. This is true of food itself, even in the absence of all preservatives. The aphorism of *caveat emptor* affords little comfort to the consumer, but in the present condition of matters it is all that can be offered him; yet it is at least due to him to know whether the food he buys is "preserved," and if so, what preservative and how much of it has been employed. But this is precisely the kind of information that purveyors of food decline to supply except under pressure of legal pains and penalties.

*The Bearings of Modern Psychology on Educational Theory and Practice.* By Christabel M. Meredith. Pp. 140. (Constable and Co., Ltd., 1916.) Price 1*s.* 6*d.* net.

THE author's aim has been "to give a brief account of some portions of recent psychological work which have had and are likely to have a special influence on education." Part i. of the little book is devoted mainly to genetic psychology, part ii. to certain special observational and experimental studies. Within her limits Mrs. Meredith has done distinctly useful work, choosing her topics with discretion and treating them in a competent and serviceable way. Her sketch of the child's mental development is based largely upon the psychological work of McDougall and Shand, whose ideas she has used skilfully in interpreting the outstanding phenomena of the nursery, the playground, and the class-room, with all of which she shows a sound first-hand familiarity. In a well-written chapter on "Experiment in Education" she brings out, by apt illustrations, the complexity of the problems which the laboratory method has to face, showing why its results must always be used with caution and at the same time that they are indispensable to progress. The final chapter on adolescence contains wisdom for parents as well as for teachers. The omission, in so slight a treatise, of a short list of books for further reading is a defect which should be remedied in a second edition.

## LETTERS TO THE EDITOR.

*[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.]*

### The Group Vermidea.

A RECENT number of NATURE (August 24, 1916, p. 525) contains a notice of a work on Nematoda, which are described as "a group of Vermidea which presents great difficulties from a systematic point of view, and has therefore been less investigated than other groups of Vermidea." It may perhaps be asked what is the justification for this use of the term "Vermidea."

In vol. v. (1897) of Delage and Hérouard's well-known "Traité de Zoologie Concrète" it is pointed out (p. 1) that Schulgin and Pruvot had independently suggested the replacement of the denomination "Molluscoïdes" [=Brachiopoda+Polyzoa] by "Vermoïdes," on the ground that the affinities of this group are with the worms rather than with the Mollusca. This idea appeared a happy one to Delage and Hérouard, who proposed to add to the group thus constituted certain small groups which they believed to have a real though distant affinity to the Polyzoa or to the Brachiopoda. The groups thus added are the Gephyrea (Priapulida, Sipunculida, and Echiurida), the Axobranchia (Vermiformiæ [=Phoronidea] and Pterobranchiæ), and the Trochelmia (Rotiferiæ, Gastrotrichiæ, Kinorhynchia, and Chætognathia). These, with the Bryozoaria [=Polyzoa] and the Brachiopodia, constitute the enlarged *embranchement*, which now appears as the "Vermidea." On p. 327 it is stated that the Vermidea "sont liés entre eux par des affinités réelles"; and the Platyhelminthes, the Nematoda, and the Annelida are definitely excluded from this association.

Up to and including vol. xlii., for 1905, the *Zoological Record* included most of the groups of "Worms" under the designation "Vermes." In vol. xliii., the first which was issued as a volume of the International Catalogue of Scientific Literature, "Vermidea" replaces "Vermes," and includes (1) Platyhelminthes, Nemertinea, Mesozoa; (2) Nemathelminthes; (3) Chætognatha, Rotifera, Gastrotricha; (4) Archiannelida, Polychæta, Oligochæta, Gephyrea, Phoronis, and Hirudinea; and to these may be added Pterobranchiata, which appears in the Contents, p. xii., though not in the formal list given at the beginning of the detailed account of the literature of these forms. I am not aware what was the authority for this use of "Vermidea"; but it may be noted that it omits the Polyzoa and the Brachiopoda, the two central groups of Delage and Hérouard's phylum; and that it includes the Platyhelminthes, Nemathelminthes, and Annelida, three groups which were expressly excluded by those authors. The group "Vermidea" of the *Zoological Record* is thus absolutely different from that of the "Traité de Zoologie Concrète." Not only does the propriety of so revolutionary a change seem questionable, but one may well ask in what way was the new departure an improvement on the old group "Vermes," which was admittedly an assemblage of forms which have no demonstrable affinity to one another. It is not possible to say much more for the grouping than that the majority of forms thus associated are invertebrates having a shape suggested by the term "worm," or, in other words, that they are longer than they are broad.

I do not desire to discuss the validity of Delage and Hérouard's phylum, although I am by no means convinced that the groups included in it are allied to one another. But in the sense in which it was defined in 1897 it indicated an attempt to advance the classification of animals. The procedure adopted by the *Zoological Record* appears to me to have nothing to recommend it. There is no doubt some convenience, from the point of view of the recorder, in dividing the animal kingdom into a small number of comprehensive groups. If the forms under consideration were described as "worms" it would be an admission that the name of the group was adopted merely for motives of convenience. The term "Vermes" was no doubt rightly rejected, since most zoologists would agree that it has no more claim to a permanent place in literature than has "Radiata," another assemblage which included animals possessing a type of symmetry which in itself is not now regarded as necessarily indicating affinity to other animals similarly provided. The use of "Vermidea" in the sense of the *Zoological Record* can only be described as pseudo-scientific. It is not only no improvement on "Vermes," but its substitution for that term is misleading, as suggesting that it is a more natural group than the one which it replaced.

SIDNEY F. HARMER.

British Museum (Natural History)
August 27.

### The Refractometry of Lenses.

IT may be of value to opticians and others to know of a method by which the refractive indices of irregular or unpolished pieces of glass, lenses, or prisms, can be found fairly accurately—*i.e.* to 1 in the fourth decimal place.

The specimen is immersed in a mixture of carbon disulphide and alcohol contained in a prism cell having refracting sides of optically plane glass; this cell is used on the table of a spectrometer.

By altering the proportions of the two liquids, the refractive index of the mixture can be made equal to that of most specimens. This is easily done by observing the image of the slit refracted through the system. The finest adjustment of proportion takes place automatically through unequal evaporation.

The *important* prevision is that the liquid must be mechanically stirred; this can be done by a small "propellor" blade driven by a motor, which must be quite separate from the spectrometer to obviate vibration.

At the proper moment the angle of minimum deviation is taken, and the refractive index calculated out in the usual way.

The method has given excellent results for refractive index and dispersion on a number of varying specimens. It should prove of use for copying optical systems. The method is at present being developed, and full details will be published shortly.

L. C. MARTIN.

Imperial College of Science and Technology,
South Kensington, London, S.W., August 23.

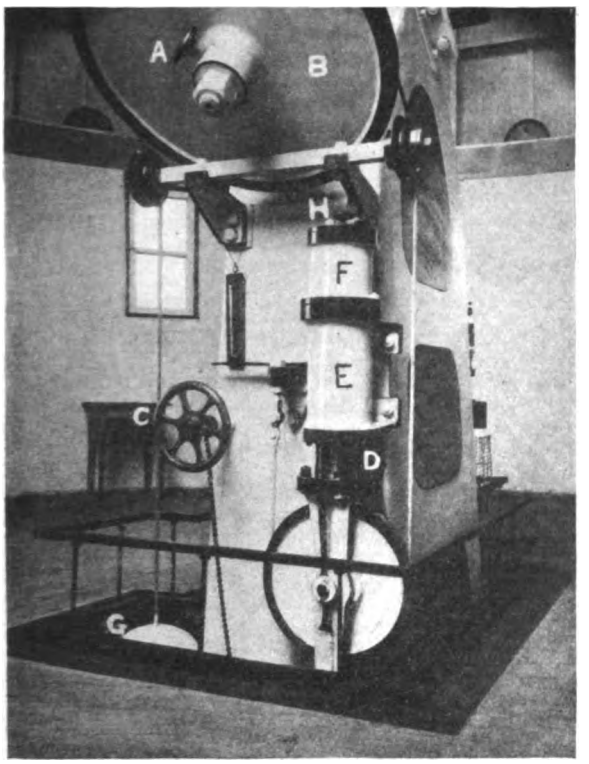
### An Oil Drive for Equatorial Telescopes.

THE drive, or oil, regulator under consideration is the invention of Mr. G. H. Denison, of Hunslet Foundry, Leeds, past president of the Leeds Astronomical Society. The device has been attached to the pedestal which carries the 26-in. reflector, and is fitted on the south side opposite the driving clock.

With the help of the accompanying photograph, the working of the device may be briefly described as follows:—

Digitized by Google

The binding screw (A) being free (or loose), the driving disc (B) is disengaged from the polar axis. On turning the winding-up wheel (C) the plunger (D) is drawn out of its cylinder (E), sucking oil into the cylinder from the reservoir (F) through a valve. The winding-up has also turned the driving disc (B) and lifted the driving weight (G). When the winding-up is finished, the cylinder (E) is full of oil, which is imprisoned by the automatic closing of the valve from the reservoir (F). The oil is now under pressure, caused by the driving weight (G), and it can only get out of the cylinder (E) back to the reservoir, through a hole, the size of which is controlled by the regulating screw (H). If the binding screw (A) is now screwed fast, the telescope will turn on its polar axis at the rate allowed by the regulating screw (H).



An oil possessing a high flash point is suitable for this purpose, since the change in viscosity under different temperatures is then not much felt. A change in the viscosity causes the oil to pass through the valve at a correspondingly different rate. Hence it is necessary to adjust the valve to the local temperature, which is done by setting the regulating screw according to the positions representing degrees of temperature, which are marked round the top of the oil reservoir. The regulator runs for three hours before re-winding, the oil, of course, being used over and over again.

In a mechanism of this nature it is evident that the question of friction is of the first importance, and great care has been taken, first, to reduce the working friction to a minimum, and, secondly, to make the unavoidable friction as constant as possible. The polar axis is therefore fitted with three sets of ball bearings (two axial and one thrust); the guide pulleys are also fitted with ball bearings, and the plunger is ground truly parallel and very smooth.

The regulator is intended more especially for eclipse and visual work in general. There are slight errors of motion which have yet to be overcome, and they render it difficult to keep a star on the wire; but by an additional contrivance which has yet to be adapted the errors in question might be reduced sufficiently to render the device suitable for stellar photography.

SCRIVEN BOLTON.

The Observatory, Bramley, Yorkshire,
August 23.

## On the "Wolf-note" of the Violin and 'Cello.

IN a letter to NATURE (June 29) on the wolf-note of the violin and 'cello which has recently come to our notice, Mr. Raman referred to a paper by one of us (G. W. W.) on the subject. We had anticipated being associated in a joint paper dealing more fully with the results when the war put an end to the work.

At the time when the preliminary results were published the cyclical variation in intensity of the wolf-note was provisionally attributed to the beating of the oscillations of the two tuned resonators, belly and string, "coupled" together by the bridge, and not to transitory beats, as perhaps justly inferred by Mr. Raman from the wording of the paper, it being assumed that the strong reaction of the belly on the string interfered with even bowing. But the later results we obtained could not be reconciled with such a view, and we were seeking an explanation on the lines of that now given by Mr. Raman.

Thus further records of the wolf-note showed very clearly indeed the prominence of the octave at the minima in the belly records. Also simultaneous records of belly and string vibrations led, in the case of one 'cello, to curves practically identical with those given by Mr. Raman, in which the maxima and minima of belly amplitude lag behind those of the string by a quarter of a cycle. With another 'cello of brilliant quality no appreciable lag appeared to exist, though perhaps better photographs would have shown some. Finally, the frequency in variation of intensity seemed to depend on the speed of the bow and not on the form of the bridge, which would affect the degree of coupling.

We take this opportunity of recording two other results obtained by us, which furnish still more evidence for the belief that the wolf-note is a phenomenon accompanying maximum resonance. They are worthy of record, because this interpretation of the effect is not that which is held generally by musicians and instrument-makers.

The first was obtained in some experiments on "the mute." With the two 'cellos with which observations were made, the effect of loading the bridge with the mute was a reduction in pitch of the wolf, by an amount depending on the form of the mute. Thus, with one heavy mute the pitch was lowered from G to D, and with a lighter mute from G to E. By blowing a cornet in front of the belly, it was found that the natural frequency of the belly was correspondingly lowered.

The second was obtained when vibrations of the belly were set up by plucking a string. The transitory beats present in the early stages of a forced oscillation were very clearly shown. The G string was plucked to give a note within a few semitones of the wolf-note. After six or seven beats the belly took up the sinusoidal vibration of the string, which persisted until the sound was no longer audible. Calculations of the natural period of the belly from the frequency of the beats led in each case to a period the same as that of the wolf-note and that given by the cornet.

## BIRDS IN STUDIO AND ON THE HILLSIDE.[1]

(1) THE second volume of Mr. Thorburn's beautiful book includes the rest of the crows, the larks, the picarian birds, the diurnal birds of prey, the owls, cormorants, and some of the herons. Many of these are large birds, and it has not been possible to figure so many of them on one plate. Two species—the golden eagle and the eagle owl—have plates to themselves, and these are most beautiful pictures. Mr. Thorburn is very successful with owls, which must be most difficult birds to paint, and he is famous for his pictures of eagles. The golden eagle is drawn flying along a steep hillside and carrying a mountain hare. The author writes that when an eagle is flying "the curious notched pinion feathers may be clearly seen, separated like the fingers of a hand." This is well shown in the plate. The introduction of certain striking plants which grow in the haunts of various birds is continued with most pleasing effect. Thus the Egyptian nightjar lies on the sand beside that thick, fleshy-leaved plant with large pink, yellow-centred flowers familiar to visitors to North Africa. The common nightjar is figured flying and thus displaying the curious white spots on the underside of the wing. As this volume includes the eagles, hawks, and falcons—favourite studies of the artist—the plates are, if anything, more pleasing than those in the first volume.

The third volume includes the rest of the herons and the allied species, and the swans, geese, ducks, pigeons, game-birds, rails, and the great bustard. The grouping of the different species on the plates is very successful; thus the swans occupy one plate, the four "grey" geese another, and the pigeons a third, thus affording the best opportunity of comparing the small differences in the colouring of allied species. The frontispiece, which shows the striking attitudes assumed by the male great bustards in spring when courting, is a fine picture. The author's acquaintance with the Scotch Highlands and their birds has served him well when treating of the black grouse and the ptarmigan, the latter forming the subject of a fine plate, while the letterpress contains some interesting observations on this bird of the mountain and the mist.

(2) Under the title "Hill Birds of Scotland" we have a charming and most interesting account of twenty-four species of birds, and are rather at a loss to know why some of them should be so designated in particular. The author's personal experiences and field notes are most interesting. But there is also introduced into the text a large amount of matter derived from other sources, and apparently sometimes from hearsay. Some of this cannot be considered as trustworthy. There are statements (for which no authority is given)

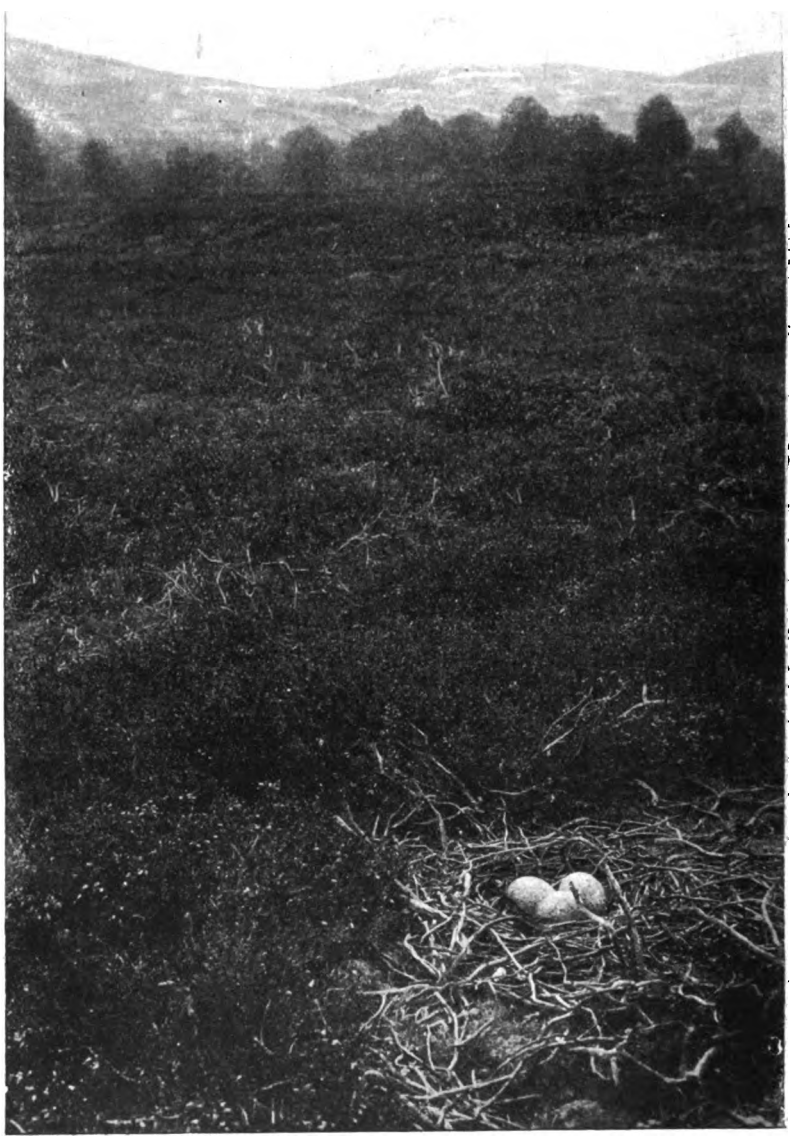

FIG. 1.—Nest of the oyster-catcher. From "Hill Birds of Scotland."

which are hard to accept and must surely have been founded on hearsay evidence, and perhaps too readily believed. We are told that when the blaeberries have ripened, the woodcocks betake themselves to the hillsides and consume great quantities of the fruit! With regard to the statement that "deer, calves, and lambs" are taken by eagles, we wonder whether this may be a slip for "deer-calves and lambs," which sounds much more likely to be true. The book might have been smaller with advantage had it been confined to the relation of the author's most valuable observations. But a considerable amount of space is occupied with descriptions of the plumage of the birds treated of, and accounts of their distribution within and outside the British islands. Both these subjects seem to us to be beyond the province of the book. The descriptions seem to be unnecessary, and in some cases inadequate, while of the accounts of distribution it must be said that they are open to criticism. For instance, we are told that "there is no bird which has so wide a range as the golden eagle—in fact, it is met with almost throughout the world."

FIG. 2.—Dotterel going to the nest. From "Hill Birds of Scotland."

One of the pleasantest chapters in the book is that on the snow bunting. A curious incident is related showing the undoubted love of coolness which drives this arctic bird to the high Scotch mountains. One very hot day a bird which usually frequented a scree was found on a dwindling snowfield seeking relief from the heat. At times he would seek to cool himself by running over the snow with his head half-buried beneath the surface, and throwing up a furrow as from a diminutive snow-plough.

The oyster-catcher (a name which we read at first with surprise among hill-birds) appears to be only a winter visitor to the eastern seaboard of Scotland—or such parts of it as the author is familiar with—and to retire to the hills to breed. Early in March oyster-catchers leave the river estuaries and make their way in pairs up the rivers—the Don and Spey, for instance. Near the source of the Spey the bird reaches, and is numerous on, a flat 1500 ft. above sea-level. We regret to read that the white-tailed eagle has decreased enormously during the last thirty years, and that there are now only two pairs of them breeding in Britain. The extermination seems to have been effected mainly by sheep farmers and shepherds, their hatred of the bird sometimes prompting them to acts of unnecessary and cold-blooded cruelty.

There are some things in the book which might well be altered in a second edition. The author thinks that in our language there is no distinctive name for the peculiar evening flight of the woodcock, and treats "Rôding" as only a Scandinavian one. But "road" is surely English, and the well-known tracks through covers pursued by woodcocks have long been called 'cock-roads. It is scarcely correct to say that prior to the nineteenth century no case of the woodcock nesting in Britain was recorded. Willughby (1678) mentions that they bred sometimes in England. White (1789) records nests, and Pennant (1776), Walcot (1789), and Lewin (1797) all record woodcocks breeding with us.

There is in the opinion of west-country ornithologists no ground for believing that the dotterel ever bred on the Mendip Hills. And the observation that this bird "is the only representative of the widely distributed and extensive group [of waders] to restrict her clutch always to three hostages to fortune" shows a want of knowledge of these birds. For, not to mention some others, the normal clutch laid by the Kentish plover consists of three eggs only.

There are between thirty and forty illustrations, the most pleasing of which show the wild scenery affected by the birds treated of. Others show the nests or young of birds, and we notice occasionally the want of consideration for the feelings and interests of both sitting and young birds, which is sometimes regrettable, on the part of enthusiastic bird-photographers.

The publishers allow us to reproduce a beautiful picture of the haunts of those oyster-catchers which go far inland and high up to breed—the hills in the background with a fresh coat of snow, and the bulky collection of dead heather stems brought together by this erratic bird when (as it does sometimes) it constructs a nest in the true sense of the term; also a photograph of a dotterel going to her nest.

## *SCIENTIFIC METHOD IN BREWING PRACTICE.*

IN his address to the Institute of Brewing, of which an abstract was published in NATURE of July 6, Dr. Horace Brown has given a very fascinating account of the gradual introduction of scientific method into the brewery, and his reminiscences, which extend over rather more than half a century, enable us to appreciate very

Digitized by Google

thoroughly the progress that has been made in this respect.

So familiar has the idea of the existence of bacteria become to the mind that some effort is required to realise the state of things fifty years ago, when brewing was carried on in total ignorance of the very existence of these ubiquitous organisms. At that comparatively recent date even the facts that yeast was a living organism and that fermentation was correlated with its growth and activity had only just been finally and definitely proved by Pasteur and were by no means universally accepted.

The recognition of these facts has placed in the hands of the brewer the means of instituting a rigorous system of control, which must be regarded as one of the most important applications of scientific method to the art of brewing. It is now recognised that infection by "disease" organisms is the cause of many of the troubles which beset the brewer, and, further, that these infecting organisms may either be bacteria or "wild" yeasts.

As in medicine, so in brewing, prevention is better than cure, and the brewer's first line of defence is the avoidance of infection from external agencies, such as dust, unsterilised casks, bottles, etc. This application of the elementary principles of bacteriology, simple as it may appear, has worked nothing less than a revolution in brewing practice, for we read that in 1865 the breweries in Burton were habitually shut down during the summer months owing to difficulties which we now know were due to infection. Another weapon in the hands of the scientific brewer is the system of "forcing"—incubating a sample of the beer for several days—whereby early information is obtained as to the stability of the beer and the presence or absence of dangerous infection. Even if infection has occurred and the dreaded *Saccharobacillus pastorianus*, which sours the beer by producing lactic acid from sugar, has increased to a dangerous extent, the yeast can be freed from it by subculture in the solution containing 0·1 per cent. of tartaric acid, which was originally proposed by Pasteur for this purpose. This purified yeast can then be used with perfect safety for pitching purposes. The statement made by Hansen that this treatment encouraged the growth of wild yeasts to a dangerous extent has not been realised in British practice.

The hops used in the production of beer provide a natural protection against bacteria, but not against "wild" yeasts, and it is to the undesired intrusion of these widely spread organisms that many faults of flavour and clarification are due. These wild yeasts grow chiefly on fruits, passing the winter and spring, as shown by Hansen, in the soil, and are therefore very abundant in dust during the late summer and autumn. They pass into the wort or beer in precisely the same manner as, for example, when the beer becomes infected after racking—they may increase rapidly and cause serious trouble. The explanation of this inhibitive action of the culture yeast on the growth of the wild yeast is due to Dr. Horace Brown, who found that the growth of all yeasts is conditioned by the amount of oxygen which is taken up by the cells before fermentation commences. This is shared between the large amount of culture yeast and the small infection, and, since the quantity of yeast present only increases some fivefold during a large-scale fermentation, no great increase in the infecting organism is possible. If, however, infection occurs after racking, when only a small proportion of primary yeast is left, and if, at the same time, air, as is usually the case, obtains access to the beer, all the conditions for a well-developed yeast trouble are at hand. To be forewarned is to be forearmed, and, the conditions which conduce to contamination having been ascertained, the brewer is in a position to avoid these as completely as possible.

A further refinement, chiefly valuable when applied in addition to the most scrupulous "bacteriological" cleanliness throughout the brewery, is the use of air which has been freed from organisms by filtration. The wort, after having been boiled, is cooled and aerated. During these processes, before the addition of the yeast, there is a manifest danger of infection by air organisms, which is largely avoided by the use at this stage of filtered air. As already pointed out, however, the main source of danger in actual practice is the infection of the beer after the primary fermentation has been completed.

One of the chief triumphs claimed for the application of scientific method to brewing is the production and use of pure yeast cultures, by which, it is maintained, greater constancy of result is obtainable. Following the principles laid down by Hansen, such cultures are derived from a single cell which is isolated under the microscope, and serves as the origin of the whole of the yeast employed. This system is largely used abroad, but has not been adopted to any great extent in this country, partly owing, no doubt, to the national inertia, but partly to the different conditions prevailing in the top-yeast breweries. This system undoubtedly keeps the pitching yeast free from contamination, but is, of course, in itself no protection against the subsequent infection by wild yeasts or bacteria, which, as we have seen, is the most frequent cause of trouble. It is, moreover, doubtful, as pointed out by Dr. Brown, whether a single-cell culture can be expected invariably to reproduce all the qualities of a stock yeast, which represent the statistical average of the properties of an immense number of cells, all differing slightly from each other.

From quite a different side the investigations of the past half-century on the action of diastase on

Digitized by Google

mashing has been to some extent revealed, and it is now possible, when necessary, intelligently to adapt the procedure to the special requirements of any particular case.

Throughout the address Dr. Brown pursues the thesis that modern surgery and preventive medicine are the children of the fermentation industries, the great development of these in recent years being primarily due to the ideas gained by Pasteur from his study of wine and beer. The argument is ably supported by an historical account of Pasteur's researches and of the gradual development of those conceptions which, partly owing to his own work and partly to that of others, led to our present views. The science of bacteriology is, however, not alone in having benefited so largely from researches on fermentation. Many other branches of science have indirectly been furthered by the study of phenomena first observed in the investigation of brewing problems. So widely, indeed, has the inspiration derived from the scientific study of brewing been diffused that the author, with pardonable enthusiasm, sums the situation in the aphorism, "Omnis Scientia ex Cerevisiâ."

## THE BRITISH ASSOCIATION AT NEWCASTLE.

THE holiday which was suddenly granted throughout the north-eastern district had a greater adverse effect than was anticipated on the attendance at the Newcastle-on-Tyne meeting of the British Association. Many who in normal times would most certainly have enrolled were far away from Newcastle enjoying a well-earned rest from their labours in connection with the manufacture of the munitions of war.

The actual total attendance was 826, so that the meeting was even a smaller one than was expected. But the only person connected with the Association who has shown any sign of disappointment is the general treasurer. He, naturally, is primarily concerned with financial matters of the Association, and a small meeting means a correspondingly small and inadequate amount available as grants towards the expenses of research committees. The rest, from the President to the members who joined recently, speak in terms of appreciation and satisfaction of both the arrangements made for them by the local committee and the work done by the sections. Locally it is generally admitted that the results obtained justified the Council of the British Association in holding a meeting this year, and the members are of the opinion that, taking into account the circumstances in which the nation stands at present, the meeting was very successful. One fact which is both interesting and significant is that, while the total number of members present was far below that of normal years, the attendance at the meetings of the Sections in Newcastle was quite up to the average. In other words, nearly everyone who attended the Newcastle meeting was a real worker and interested in the chief object for which the British Association was founded, viz., the advancement of science.

One of the outstanding features of the meeting, from the local point of view especially, was the election of the Hon. Sir Charles A. Parsons to the Presidency of the Association for the meeting next year. His name is a household word on the north-east coast, and any honour done him is genuinely appreciated by the residents, more especially the engineers and shipbuilders. Nor can we help mentioning an incident that happened on the last day of the meeting. It was small in itself, but it was kindly and gracious, and it helped to sow the seed from which will spring a still heartier welcome to the British Association than it has previously received in Newcastle, if that were possible. Owing to the scarcity of adult labour a troop of Boy Scouts was employed to act as messengers between the reception room and the Section rooms. These lads did their work admirably; they carried out their instructions to the letter, and earned the praise of the local committee as well as of the general officers. On the closing morning of the meeting those who happened to be in the vicinity of the reception room fairly early were glad to hear Prof. H. H. Turner thank the boys for their services and explain the objects and work of the British Association in a manner that helped them not only to go away feeling that they had rendered good service, but also with an ambition to become members in time to come.

The proceedings of all the sections were well up to the usual standard, both as regards interest and value. Among the subjects of important discussions were the investigation of the chemical and geological characters of different varieties of coal, with a view to their most effective utilisation as fuel, and to the extraction of by-products; science in education and industry; the effects of the war upon credit, currency, and finance; national aspects of fuel economy; the development of fisheries; political frontiers; and afforestation. Some of the main points brought out in these discussions will be described in later issues.

The General Committee adopted a recommendation of the Council that research committees should have power to report through organising committees of Sections to the Council at any time when the Association is not in annual session. Hitherto research committees have had to await the annual meeting before presenting their reports, even when their conclusions call for early action. Under the new rules this will no longer be necessary if the organising committee to which a research committee presents its report considers it desirable to report direct to the Council. Another alteration of the rules of the Association makes it possible for the Council to include upon research committees persons who are not members of the Association, but "whose assistance may be regarded as of special importance to the research undertaken."

Digitized by Google

The general treasurer has reported to the Council that Mr. M. Deshumbert proposed to leave a legacy of about 5000*l.* to the Association, subject to the condition that his wife and her sister should receive the interest during their lifetime.

The new members of Council elected by the General Committee are Mr. R. A. Gregory, Dr. S. F. Harmer, Dr. E. J. Russell, Dr. A. Strahan, and Prof. W. R. Scott. An invitation to meet in Cardiff in 1918 was unanimously and gratefully accepted by the Committee.

The total grants of money appropriated by the General Committee for purposes of research committees proposed by the various sections amounted to 602*l.* The subjects and grants are as follows:—

*Section A.*—Seismological observations, 100*l.*; annual tables of constants, 40*l.*; mathematical tables, 20*l.*; gravity at sea, 10*l.*

*Section B.*—Dynamic isomerism, 15*l.*; Eucalypts, 30*l.*; absorption spectra, etc., of organic compounds, 10*l.*

*Section C.*—Red Sandstone rocks of Kiltorcan, 4*l.*; Palæozoic rocks, 20*l.*

*Section D.*—Biology of the Abrolhos Islands, 6*l.*; inheritance in silkworms, 20*l.*

*Section F.*—Fatigue from an economic point of view, 40*l.*; replacement of men by women in industry, 20*l.*; effects of war on credit, etc., 10*l.*

*Section G.*—Stress distributions, 40*l.*

*Section H.*—Artificial islands in the lochs of the Highlands of Scotland, 5*l.*; physical characters of ancient Egyptians, 2*l.* 12*s.* (unexpended balance); Palæolithic site in Jersey, 30*l.*; excavations in Malta, 20*l.*; distribution of Bronze age implements, 1*l.* 14*s.* (unexpended balance).

*Section I.*—Ductless glands, 15*l.*; psychological war research, 10*l.*

*Section K.*—Physiology of heredity, 45*l.*; ecology of fungi, 8*l.*

*Section L.*—School books and eyesight, 5*l.*; work of museums in education and research, 15*l.*; effects of "free-place" system upon education, 15*l.*; science teaching in secondary schools, 10*l.*; mental and physical factors involved in education, 10*l.*

*Corresponding Societies' Committee.*—For preparation of report, 25*l.*

## SECTION B.

### CHEMISTRY.

OPENING ADDRESS (ABRIDGED) BY PROF. G. G. HENDERSON, D.Sc., LL.D., F.R.S., PRESIDENT OF THE SECTION.

THE period which has elapsed since the last meeting of the section in Newcastle has witnessed truly remarkable progress in every branch of pure and applied chemistry. For fully fifty years previous to that meeting the attention of the great majority of chemists had been devoted to organic chemistry, but since 1885, or thereabouts, whilst the study of the compounds of carbon has been pursued with unflagging energy and success, it has no longer so largely monopolised the activities of investigators. Interest in the other elements, which had been to some extent neglected on account of the fascinations of carbon, has been revived with the happiest results, for not only has our knowledge of these elements been greatly extended, but their number also has been notably increased by the discovery of two groups of simple substances possessed of new and remarkable properties—the inert gases of the argon family and the radio-active elements. In addition, the bonds between mathematics and physics on one hand and chemistry on the other have been drawn closer, with the effect that the department of our science known as physical chemistry has now assumed a position of first-rate importance. With the additional light provided by the development and application of physico-chemical theory and methods, we are beginning to gain some insight into such intricate problems as the relation between physical properties and chemical constitution, the structure of molecules and even of atoms, and the mechanics of chemical change; our outlook is being widened, and our conceptions rendered more precise. Striking advances have also been made in other directions. The extremely difficult problems which confront the biochemist are being gradually overcome, thanks to the indefatigable labours of a band of highly skilled observers, and the department of biological chemistry has been established on a firm footing through the encouraging results obtained within the period under review. Further, within the last few years many of our ideas have been subjected to a revolutionary change through the study of the radio-active elements.

The more purely scientific side of our science can claim no monopoly in progress, for applied chemistry, in every department, has likewise advanced with giant strides, mainly, of course, through the application of the results of scientific research to industrial purposes. Many of the more striking results in the field of modern chemical industry have been obtained by taking advantage of the powers we now possess to carry out operations economically both at very high and at very low temperatures, and by the employment on the manufacturing scale of electrolytic and catalytic methods of production. Thanks largely to the invention of the dynamo, the technologist is now able to utilise electrical energy both for the production of high temperatures in the different types of electric furnace and for electrolytic processes of the most varied description. Among the operations carried out with the help of the electric furnace may be mentioned the manufacture of graphite, silicon, and phosphorus; of chromium and other metals; of carbides, silicides, and nitrides; and the smelting and refining of iron and steel. Calcium carbide claims a prominent place in the list, in the first place because of the ease with which it yields acetylene, which is not only used as an illuminant, and, in the oxy-acetylene burner, as a means of producing a temperature so high that the cutting and welding of steel is now a comparatively simple matter, but also promises to serve as the starting-point for the industrial synthesis of acetaldehyde and many other valuable organic compounds. Moreover, calcium carbide is readily converted in the electric furnace into calcium cyanamide, which is employed as an efficient fertiliser in place of sodium nitrate or ammonium sulphate, and as a source of ammonia and of alkali cyanides. Among the silicides carborundum is increasingly used as an abrasive and a refractory material, and calcium silicide, which is now a commercial product, forms a constituent of some blasting explosives. The Serpek process for the preparation of alumina and ammonia, by the formation of aluminium nitride from bauxite in the electric furnace, and its subsequent decomposition by caustic soda, should also be mentioned. Further, the electric furnace has made possible the manufacture of silica apparatus of all kinds, both for the laboratory and the works, and of alundum ware, also used for operations at high temperature. Finally, the first step in the manufacture of nitric acid and of nitrites from air, now in operation on

Digitized by Google

a very large scale, is the combustion of nitrogen in the electric arc.

In other industrial operations the high temperature which is necessary is obtained by the help of the oxy-hydrogen or the oxy-acetylene flame, the former being used, amongst other purposes, in a small but, I believe, profitable industry, the manufacture of synthetic rubies, sapphires, and spinels. Also, with a comparatively recent period, advantage has been taken of the characteristic properties of aluminium, now obtainable at a moderate price, in the various operations classed under the heading alumino-thermy, the most important being the reduction of refractory metallic oxides, although, of course, thermite is useful for the production of high temperatures locally.

The modern methods of liquefying gases, which have been developed within the period under review, have rendered possible research work of absorbing interest on the effect of very low temperatures on the properties and chemical activity of many substances, and have been applied, for instance, in separating from one another the members of the argon family, and in obtaining ozone in a state of practical purity. Moreover, industrial applications of these methods are not lacking, amongst which I may mention the separation of nitrogen and oxygen from air, and of hydrogen from water-gas—processes which have helped to make these elements available for economic use on the large scale.

Electrolytic methods are now extensively employed in the manufacture of both inorganic and organic substances, and older processes are being displaced by these modern rivals in steadily increasing number. It is sufficient to refer to the preparation of sodium, magnesium, calcium, and aluminium, by electrolysis of fused compounds of these metals; the refining of iron, copper, silver, and gold; the extraction of gold and nickel from solution; the recovery of tin from waste tin-plate; the preparation of caustic alkalis (and simultaneously of chlorine), of hypochlorites, chlorates, and perchlorates, of hydrosulphites, of permanganates and ferricyanides, of persulphates and percarbonates; the regeneration of chromic acid from chromium salts; the preparation of hydrogen and oxygen. As regards organic compounds, we find chiefly in use electrolytic methods of reduction, which are specially effective in the case of many nitro-compounds, and of oxidation, as, for instance, the conversion of anthracene into anthraquinone. At the same time a number of other compounds, for example, iodoform, are also prepared electrolytically.

Within recent years there have been great advances in the application of catalytic methods to industrial purposes. Some processes of this class have, of course, been in use for a considerable time, for example, the Deacon chlorine process and the contact method for the manufacture of sulphuric acid, whilst the preparation of phthalic anhydride (largely used in the synthesis of indigo and other dyestuffs), by the oxidation of naphthalene with sulphuric acid with the assistance of mercuric sulphate as catalyst, is no novelty. More recent are the contact methods of obtaining ammonia by the direct combination of nitrogen and hydrogen, and of oxidising ammonia to nitric acid—both of which are said to be in operation on a very large scale in Germany. The catalytic action of metals, particularly nickel and copper, is utilised in processes of hydrogenation—for example, the hardening of fats, and of dehydrogenation, as in the preparation of acetaldehyde from alcohol, and such metallic oxides as alumina and thoria can be used for processes of dehydration—*e.g.* the preparation of ethylene or of ether from alcohol. Other catalysts employed in industrial processes are titanous chloride in electrolytic reductions and cerous sulphate in electrolytic oxidations of carbon compounds, gelatine in the preparation of hydrazine from ammonia, sodium in the synthesis of rubber, etc.

Other advances in manufacturing chemistry include the preparation of a number of the rarer elements and their compounds, which were scarcely known thirty years ago, but which now find commercial applications. Included in this category are titanium, vanadium, tungsten, and tantalum, now used in metallurgy or for electric lamp filaments; thoria and ceria in the form of mantles for incandescent lamps; pyrophoric alloys of cerium and other metals; zirconia, which appears to be a most valuable refractory material; and compounds of radium and of mesothorium, for medical use as well as for research. Hydrogen, together with oxygen and nitrogen, are in demand for synthetic purposes, and the first also for lighter-than-air craft. Ozone is considerably used for sterilising water and as an oxidising agent; for example, in the preparation of vanillin from *iso*eugenol, and hydrogen peroxide, now obtainable very pure in concentrated solution, and the peroxides of a number of the metals are also utilised in many different ways. The per-acids—perboric, percarbonic, and persulphuric—or their salts are employed for oxidising and bleaching purposes, and sodium hydrosulphite is much in demand as a reducing agent —*e.g.* in dyeing with indigo. Hydroxylamine and hydrazine are used in considerable quantity, and the manufacture of cyanides by one or other of the modern methods has become quite an important industry, mainly owing to the use of the alkali salts in the cyanide process of gold extraction. Those remarkable compounds, the metallic carbonyls, have been investigated, and nickel carbonyl is employed on the commercial scale in the extraction of the metal. Fine chemicals for analysis and research are now supplied, as a matter of course, in a state of purity rarely attained a quarter of a century ago.

In the organic chemical industry similar continued progress is to be noted. Accessions are constantly being made to the already enormous list of synthetic dyes, not only by the addition of new members to existing groups, but also by the discovery of entirely new classes of tinctorial compounds; natural indigo seems doomed to share the fate of alizarine from madder, and to be ousted by synthetic indigo, of which, moreover, a number of useful derivatives are also made. Synthetic drugs of all kinds—antipyrine and phenacetin, sulphonal and veronal, novacain and β-eucaine, salol and aspirin, piperazine and adrenaline, atoxyl and salvarsan—are produced in large quantities, as also are many synthetic perfumes and flavouring materials, such as ionone, heliotropine, and vanillin. Cellulose in the form of artificial silk is much used as a new textile material, synthetic camphor is on the market, synthetic rubber is said to be produced in considerable quantity; and the manufacture of materials for photographic work and of organic compounds for research purposes is no small part of the industry.

British chemists are entitled to regard with satisfaction the part which they have taken in the development of scientific chemistry during the last three decades, as in the past, but with respect to the progress of industrial chemistry it must be regretfully admitted that, except in isolated cases, we have failed to keep pace with our competitors. A number of different causes have contributed to bring about this state of affairs, and the responsibility for it is assigned by some to the Government, by others to the chemical manufacturers, and by still others to the professors of chemistry. I think, however, it will be generally admitted that the root of the matter is to be found in the general ignorance of and indifference to, the

Digitized by Google

methods and results of scientific work which characterise the people of this country.

The Government has taken a most significant step in advance by appointing an Advisory Council for Scientific and Industrial Research, and providing it with funds; incidentally, in so doing, it has recognised the past failure of the State to afford adequate support to scientific work.

It is safe to prophesy that the money expended by the Advisory Council will sooner or later yield a goodly return, and this justifies the hope that the Government will not rest satisfied with their achievement, but will take further steps in the same direction. This desire for continued action finds strong support in the recommendations made by a Sub-Committee of the Advisory Committee to the Board of Trade on Commercial Intelligence, which was appointed to report with respect to measures for securing the position, after the war, of certain branches of British industry. Of these recommendations I quote the following:—

"*Scientific Industrial Research and Training.* (*a*) Larger funds should be placed at the disposal of the new Committee of the Privy Council, and also of the Board of Education, for the promotion of scientific and industrial training. (*b*) The universities should be encouraged to maintain and extend research work devoted to the main industry or industries located in their respective districts, and manufacturers engaged in these industries should be encouraged to co-operate with the universities in such work, either through their existing trade associations or through associations specially formed for the purpose. Such associations should bring to the knowledge of the universities the difficulties and needs of the industries, and give financial and other assistance in addition to that afforded by the State. In the case of non-localised industries trade associations should be advised to seek, in respect of centres for research, the guidance of the Advisory Committee of the Privy Council. (*c*) An authoritative record of consultant men of science, chemists, and engineers, and of persons engaged in industrial research, should be established and maintained by some suitable Government Department for the use of manufacturers only."

The admirable scheme of the Australian Government is more comprehensive and more generous than that of our Government, but it could be rivalled without much difficulty. We already possess an important asset in the National Physical Laboratory, and there now exists the Advisory Council with its extensive powers and duties. What is lacking in our scheme, so far as chemistry is concerned, could be made good, first, by providing the Advisory Council with much larger funds, and secondly, by the establishment of a National Chemical Laboratory—an institute for research in pure and applied chemistry—or by assisting the development of research departments in our universities and technical colleges (as is now being done in America), or, better still, by moving in both directions. With respect to the second alternative, I do not mean to suggest that research work is neglected in the chemistry departments of any of our higher institutions; what I plead for is the provision of greater facilities for the prosecution of investigation not only in pure but also in applied chemistry. As things are at present, the professors and lecturers are for the most part so much occupied in teaching and in administration as to be unable to devote time uninterruptedly to research work, which demands above all things continuity of effort. The ideal remedy would be the institution of research professorships, but, failing this, the burden of teaching and administrative work should be lightened by appointing larger staffs.

Unless the conditions and methods which have ruled in the past are greatly altered it is scarcely possible to hope that the future prospects of our chemical industry will be bright; it is essential that the representatives of the industry should organise themselves in their own interest and co-operate in fighting the common enemy. More than ever is this the case when, as we are informed, three different groups of German producers of dyes, drugs, and fine chemicals, who own seven large factories, have formed a combination with a capital of more than 11,000,000*l*., and with other assets of very great value in the shape of scientific, technical, and financial efficiency. Hence it is eminently satisfactory to be able to record the active progress of a movement, originated by the Chemical Society, which has culminated in the formation of an Association of British Chemical Manufacturers.

Needless to say, the progress of this important movement will be assisted by everyone who is interested, either directly or indirectly, in the welfare of our chemical industry, and, moreover, the support of the scientific societies will not be lacking.

In an address given to the Society of Chemical Industry last year, I indicated another way in which chemical manufacturers can help themselves and at the same time promote the interests of chemistry in this country. In the United States of America individual manufacturers, or associations of manufacturers, have shown themselves ready to take up the scheme originated by the late Prof. Duncan for the institution of industrial research scholarships tenable at the universities or technical colleges, and the results obtained after ten years' experience of the working of this practical method of promoting co-operation between science and industry have more than justified the anticipations of its originator. The scheme is worthy of adoption on many grounds, of which the chief are that it provides definite subjects for technical research to young chemists qualified for such work, that it usually leads to positions in factories for chemists who have proved their capacity through the work done while holding scholarships, and that it reacts for good on the profession generally, by bringing about that more intimate intercourse between teachers and manufacturers which is so much to be desired.

It cannot be too often reiterated that no branch of chemical industry can afford to stand still, for there is no finality in manufacturing processes; all are capable of improvement, and for this, as well as for the discovery and the application of new processes, the services of the trained chemist are essential. Hence the training of chemists for industrial work is a matter of supreme importance. We may therefore congratulate ourselves that the opportunities for chemical instruction in this country are immensely greater than they were thirty years ago. The claims of chemistry to a leading position have been recognised by all our universities, even the most ancient, by the provision of teaching staffs, laboratories, and equipment on a fairly adequate if not a lavish scale, and in this respect many of the technical colleges fall not far behind. The evening classes conducted in a large number of technical institutions are scarcely fitted to produce fully trained chemists, if only because lack of the necessary time prevents the student from obtaining that prolonged practice in the laboratory which cannot be dispensed with, unless indeed he is prepared to go through a course of study extending over many years. At the same time these evening classes play a most important part, first, in disseminating a knowledge of chemistry throughout the country, and, secondly, in affording instruction of a high order in special branches of applied chemistry. Finally, in a large and increasing number of schools a more or less satisfactory introduction to the science is given by well-qualified teachers. With our national habit of self-depreciation we are apt to overlook the steady progress which has

Digitized by Google

been made, but at the same time I do not suggest that there is no room for improvement of our system of training chemists. Progress in every department of industrial chemistry is ultimately dependent upon research, and therefore a sufficient supply of chemists with practical knowledge and experience of the methods of research is vital. This being so, it is an unfortunate thing that so many students are allowed to leave the universities in possession of a science degree but without any experience in investigation. The training of the chemist, so far as that training can be given in a teaching institution, must be regarded as incomplete unless it includes some research work, not, of course, because every student has the mental gifts which characterise the born investigator, but rather because of the inestimable value of the experience gained when he has to leave the beaten track and to place more dependence upon his own initiative and resource. Perhaps it is too much to expect that practice in research will be made an indispensable qualification for the ordinary degree; failing this, and indeed in every case, promising students should be encouraged, by the award of research scholarships, to continue their studies for a period of at least two years after taking the B.Sc. degree, and to devote that time to research work which would qualify for a higher degree.

On more than one occasion I have expressed the opinion that every chemist who looks forward to an industrial post should receive in the course of his training a certain amount of instruction in chemical engineering, by means of lectures and also of practical work in laboratories fitted out for the purpose. The practicability of this has been proved in more than one teaching institution, and experience has convinced me that chemists who have had such a course are generally more valuable in a works—whether their ultimate destination is the industrial research laboratory or the control of manufacturing operations—than those who have not had their studies directed beyond the traditional boundaries of pure chemistry. A course in chemical engineering, preferably preceded by a short course in general engineering and drawing, must, however, be introduced as *a supplement to*, and not as *a substitute for*, any part of the necessary work in pure chemistry, and consequently the period of undergraduate study will be lengthened if such a course is included; this is no disadvantage, but quite the contrary. I am glad to say that the University of Glasgow has recently instituted a degree in applied chemistry, for which the curriculum includes chemical engineering in addition to the usual courses in chemistry, and I hope that a place will be found for this subject by other universities.

## NOTES.

THE King in Council has appointed Mr. Arthur Henderson, M.P., a member of the Committee of the Privy Council for the organisation and development of scientific and industrial research. The other non-official members of the Committee are Lord Haldane, the Right Hon. A. H. D. Acland, and the Right Hon. A. Pease, M.P. Mr. Henderson was the President of the Board of Education when the Government's research scheme was published in July of last year. As such he was a member of the Committee, which includes also, as official members, the Lord President of the Privy Council, the Chancellor of the Exchequer, the Secretary for Scotland, the President of the Board of Trade, and the Chief Secretary for Ireland.

BY permission of the president and council of the Royal Academy an Exhibition of Arts and Crafts is to be held in the galleries of the Royal Academy from October 2 until the end of November next. The exhibition is being arranged by the Arts and Crafts Exhibition Society.

WE are informed that the Secretary of State for India has sanctioned the creation of a post of Director of Fisheries, Bengal, Bihar, and Orissa, and has further sanctioned the permanent appointment of the present Deputy Director of Fisheries (Mr. T. Southwell) to the post. A new Deputy Director will be appointed after the war.

THE death is announced, at sixty-eight years of age, of Sir James Sivewright, K.C.M.G., general manager of the South African Telegraphs, 1877–85, and Commissioner of Crown Lands and Public Works, Cape Colony, 1890–92, when he promoted considerable developments of the railway and telegraphic systems.

OXFORD has lately become poorer by the loss of two of her best-known sons, each in his own way distinguished as well outside the University as within it. During a long residence in Oxford Mr. R. W. Doyne, formerly Margaret Ogilvie reader in ophthalmology, whose career and work were referred to last week (p. 18), had won the respect and affection of colleagues and pupils alike. Dr. Edward Moore, as a young man, had one of the most distinguished academic careers on record. The chief efforts of his mature life were directed towards the welfare and independence of St. Edmund Hall, one of the most interesting of the ancient institutions of Oxford. Consistently conservative in his attitude towards academic questions, there was yet no trace of bigotry or bitterness in his opposition to changes which he thought ill-considered or dangerous. His death at the age of eighty-one removes one whose personal qualities endeared him to an unusually wide circle.

BY the death, on August 28, of Mr. George Coffey, Ireland has lost her foremost student of prehistoric archæology. The Neolithic and Bronze periods are represented in Ireland by a very fine series of monument, weapons, and other remains, and Mr. Coffey made these his special study, applying to them, almost for the first time, the knowledge gained by his French and Scandinavian colleagues from the important series of remains which have been brought to light during recent years in western Europe. He devoted special attention to the history of primitive art in Ireland, and by tracing the development of ornament and applying it to the monuments and other early remains of that country, he did much to establish the sequence of Irish prehistoric history. More recent periods also claimed his attention, and in his "Guide to the Celtic Antiquities of the Christian Period" preserved in the Royal Irish Academy collection in the Dublin National Museum (where for many years he was keeper of the Irish antiquities), he gave a scholarly account of the beautiful work of early historic times in Ireland.

THE death of Dr. C. T. Clough, of H.M. Geological Survey, by an accident on the railway near Bo'ness, has brought to a close a career of remarkable devotion to geological work. On Wednesday, August 23, Dr. Clough was examining rock exposures in the Bo'ness coalfield, and had occasion to cross the railway. He failed to clear an approaching train and was run over. Receiving immediate attention from the railway staff, he was sent by special train to Edinburgh, where an operation was performed. For a time he seemed to recover strength, but early on Sunday, August 27, he died in Edinburgh Infirmary. Dr. Clough was educated at Rugby and St. John's College, Cambridge,

Digitized by Google

and joined the Geological Survey about forty years ago. His first work was done in the north of England; he was afterwards transferred to Scotland, and at the time of his death was senior District Geologist on the Scottish branch of the Geological Survey. Field work in difficult country had an especial attraction for him, and the minuteness and accuracy of his mapping on the six-inch scale were really astonishing. For many years most of his time was spent in the Highlands, in Cowal, the Loch Maree district, western Sutherlandshire, Glenelg, Strathcarron, and Glen Etive. He also surveyed Soay and part of Skye, and for the last ten years he had been in charge of the survey's work in Mull. Since 1901 Dr. Clough spent part of each year in the revision of the maps of the Scottish coalfields, and at first in the Lothian coalfield, later in the Wishaw, Holytown, and Bo'ness coalfields, he produced maps of unrivalled detail and completeness. Of late years he was in charge of the revision of the North Ayrshire field, and himself mapped the Kilmarnock district. A man of singular gentleness, patience, and modesty, Dr. Clough was beloved by all with whom he came in contact. Most of his contributions to geology have been published in survey memoirs. The Geological Society in 1906 awarded him the Murchison medal. In July of the present year the University of St. Andrews conferred on him the honorary degree of LL.D. He was a past-president of the Edinburgh Geological Society.

MANY readers of NATURE will have read with regret of the death, at the age of 62, of Mr. F. W. Frankland on July 23, at New York. Mr. Frankland was the eldest son of the late Sir Edward Frankland, K.C.B., F.R.S.; his brilliant career as a student at University College, London, was cut short by a breakdown in health in consequence of which he was recommended to proceed to New Zealand in 1875. On recovery he turned his great mathematical talents to account by entering the newly created Government Insurance Department of that colony, ultimately becoming Government Insurance Commissioner and Government Actuary and Statist and Registrar of Friendly Societies of New Zealand. He represented New Zealand as statistical delegate at the International Congress of Hygiene and Demography held in London in 1891. At University College, Frankland was one of the late Prof. W. K. Clifford's most distinguished students, and enjoyed a close intellectual intimacy both with him and with Herbert Spencer, and although the academic career for which he was so eminently fitted had been rendered impossible by his ill-health, he continued throughout life zealously to pursue his mathematical and philosophical studies and speculations. Already as a student in 1870 he had, independently of Clifford, arrived at that theory, or doctrine, of existence known as "mind-stuff," a paper on which he communicated to the Wellington (N.Z.) Philosophical Society in 1879; another paper, entitled "On the Metaphysic of Space," was communicated to the now defunct Philosophical Society of London, of which he became a member in 1885. He later evolved a theory of time in which he contended that time, like all else, has existence only in minds, and that the time-process is the dialectical concatenation of a series of "atomic *nows*" in the universe of awareness. In his mathematical speculations he was more especially drawn into the transcendental geometry of Lobatchewsky and Riemann, and in this domain he contributed papers "On the Simplest Continuous Manifoldness of Two Dimensions and of Finite Extent" to the London Mathematical Society (vol. viii., No. 107), and on the "Theory of Discrete Manifolds" to the American Mathematical Society in 1897. Always alive to the possibility of the scientific expansion and improvement in life insurance methods, Frankland originated and introduced in New Zealand the regulation that in the registration of the deaths of males the particulars of the family left should also be recorded, and the data so obtained have been found of great value by actuaries at home and elsewhere. His original views on a great variety of subjects are briefly outlined in "Thoughts on Ultimate Problems," published by David Nutt.

WE notice with regret the report from the Christiania correspondent of the *Morning Post* that Prof. H. Mohn, the well-known meteorologist, died on September 12, at eighty years of age.

THE death is announced, in his seventy-fourth year, of Mr. G. A. Hill, who was a tutor in chemistry at Harvard from 1865 to 1871, and assistant-professor of physics from 1871 to 1876. From 1898 to 1914 he was director of the Nolan laboratory for college preparation in physics and chemistry. He was the author, and joint author, of several text-books in mathematics and physics.

MR. LANSING, the American Secretary of State, has formally announced the signature of a Treaty with Great Britain for the protection of migratory birds. It will apply mainly to the migration of game and insect-eating birds from the United States to Canada. This is the first Treaty of the kind into which the American Government has entered.

NEWS has been received in America of the death of Mr. W. S. Lyon, the leading authority on botany and horticulture in the Philippine Islands, where he had been living since 1902. He had previously served as head of the California State Board of Forestry, and while holding this position had made, at the request of Prof. Asa Gray, a complete and valuable collection of the flora of the Catalina Islands.

MR. R. F. GRIGGS, who has been making an expedition to the Katmai volcano in the interests of the American Geographic Society, has returned to Kodiak, Alaska, and reports that its main crater is one of the largest in the world. It is miles across, and extends down thousands of feet to a blue-green lake, shimmering and sputtering at the bottom. The most wonderful of all sights at the crater was a place where a glacier, blown in two by the great eruption in June, 1912, still formed part of the crater wall, the intense heat being insufficient to melt this palisade of ice. Part of the crater wall is composed of igneous rock of brilliant colour.

SIX members of the Stefansson Arctic Expedition, under the leadership of Dr. Rudolph Anderson, have arrived at Nome, all of them in good physical condition. They reported that Stefansson himself is remaining in the Arctic to continue his exploration of the land he has discovered north of Prince Patrick Land, and that he is not likely to return during the present season. He left Dr. Anderson's party to the south of these lands that they might explore more thoroughly the Canadian continental line. They have mapped the coast-line from the Cape Parry Peninsula for a considerable distance east, and have made topographical and geological surveys of a huge region which lies half-way between northern Alaska and the outlet of Hudson Bay. Sir John Franklin's charts have been corrected, large copper fields have been discovered, and ethnological and other scientific information has been obtained.

ABOUT forty years ago a series of primitive mining implements was discovered in the old copper mines at Alderley Edge, Cheshire, which excited great

Digitized by Google

interest. They were described by Prof. Boyd Dawkins in vol. v. (1876) of the Journal of the Anthropological Institute, who divided them into three classes:—(1) Hammers with a simple groove round the middle for the retention of the withy which formed the handle; (2) tools which, besides this groove, had one of their ends also grooved for the reception of a second withy, and thus were prevented from slipping when a blow was struck; (3) two implements which seemed to be wedges. Prof. Boyd Dawkins was inclined to believe that they were of pre-Roman age. Further examples of the same type were discovered a few years ago by Mr. F. S. Graves, who has contributed three specimens to the Hull Museum. They are made of glacier-borne erratics of igneous rock, carefully trimmed into shape. These interesting survivals of early mining are illustrated and described in No. 108 of the Hull Museum Publications.

ROCKY MOUNTAIN spotted fever is a typhus-fever-like disease occurring in limited areas in North America. So far no micro-organism has been definitely found associated with it. Wolbach now describes a bacterium having certain peculiar characters, which may be found in large numbers in the lesions characteristic of spotted fever in experimental animals. It is well stained with Giemsa's stain, which is not usual with bacteria, possesses low specific gravity, as it is not thrown down by centrifuging, and cannot be cultivated (*Journ. Med. Research*, xxxiv., 1916, p. 121).

THE subject of the filterability of micro-organisms through a porcelain filter is one of considerable interest and importance. The pores of such a filter are so fine that particles passing through them are usually beyond the limit of microscopic vision, and the viruses of several diseases are known to be of this nature. The possibility of easily visible micro-organisms having a sub-microscopic filterable stage has also to be considered. Wolbach shows that certain spiral organisms larger than many bacteria, viz. *Spirochaeta duttoni* of African tick fever, *Sp. elusa*, and *Sp. biflexa*, will pass through the pores of Berkefeld V, N, and W filters (*Amer. Journ. Tropical Diseases and Prevent. Med.*, ii., February, 1915, p. 494). On the other hand, trypanosomes from cultures and from animal tissues are not filterable through bacteria-proof filters (Wolbach, Chapman, and Stevens, *Journ. Med. Research*, xxxiii., 1915, p. 107).

THE fourteenth annual report of the Imperial Cancer Research Fund recently issued gives evidence of the effects of war-time conditions on the investigations. In spite of the depleted staff the essential organisation is being maintained, and a number of papers were published by the director and assistants. The studies of Dr. Tsurumi on heterologous tumour immunity constitute an attempt at biochemical analysis of new growths by testing the reactions to blood and tissue extracts of the sera of rabbits immunised against mouse and rat tumours. The hæmolytic and agglutinating properties were found to correspond to the specific protein reactions of mouse and rat tissues. Complement fixation gave indications of common properties in tumours of like histological types. A preliminary account was published of an interesting guinea-pig tumour, a lipo-sarcoma. The relation of the mitochondria to the development of fat in the cells of this growth showed that this process is to be regarded as a differentiation, and not as a fatty degeneration such as is common in the majority of rapidly growing neoplasms. Brief reference is made to unpublished work by the director on the relation of the anti-ferment power of the blood, to the phenomena of the Abderhalden reaction, and to an investigation by Dr. Cramer of the relation of the water content of transplantable carcinomata to rate of growth and other biological characters.

DR. F. H. EDGEWORTH publishes in the July issue of the *Quarterly Journal of Microscopical Science* results of his studies on the development and morphology of the pharyngeal, laryngeal, and hypobranchial muscles of mammals. The paper is a continuation of one published in that journal during 1914. The author is to be congratulated on the completion of his task, which must have entailed an enormous amount of labour.

THE Transactions of the Royal Scottish Arboricultural Society for July, 1916, contain an article by James W. Munro on the insects attacking the common pine in Scotland. Their life-history, which he has studied for some years, is traced in connection with the mode of felling of the timber, which leaves the felled area covered with branches and stumps. Mr. D. E. Hutchins records as a sign of progress the recent appointment of Mr. Lane Poole, a competent forester trained at Nancy, as chief forest officer in Western Australia. This post had been left vacant for twelve years, though the forests of this State are of great value, consisting mainly of karri and jarrah, two of the finest species of Eucalyptus.

IN *British Birds* for August Mr. J. H. Owen continues his notes on the breeding habits of the sparrow-hawk. He describes now the behaviour of the male, which, it would seem, takes no part in the incubation of the eggs, though he feeds the female during both the laying and incubating periods. The food he brings her is never eaten at the nest, but on some tree at a little distance therefrom, to which she flies when called by her mate. Sometimes the transference of food takes place in mid-air, but as a rule it is brought to the tree. As the date of hatching approaches she shows less and less inclination to leave the nest, so that the last days of incubation are passed fasting. The male never feeds the young, so that if the female is killed these must starve. He will bring food and leave it at the nest, but lacks the instinct to break up and distribute it among his offspring. The young, it would seem, are quite unable to feed themselves until they are three weeks old.

AN interesting series of papers on muscle physiology appeared in the May number of the *American Journal of Physiology* by Prof. Frederic S. Lee and his colleagues at Columbia University, New York. In the first place, it is shown that the diaphragm takes the leading position among the skeletal muscles, as regards its power of work, and its efficiency is correlated with its richness in glycogen. The effects of temperature and humidity were also examined in cats' muscles. The cats were arranged in three series: (*a*) after exposure for six hours to 21° C. and 52 per cent. humidity; (*b*) 24° C. and 70 per cent. humidity; and (*c*) 33° C. and 90 per cent. humidity. The muscles were excised, stimulated to exhaustion, and the total work measured. The following percentages express the duration of the working period: (*a*) 100, (*b*) 97, and (*c*) 89; and the total work was (*a*) 110, (*b*) 85, (*c*) 76. The total blood per kilogram of body-weight was decreased in the cats exposed to the higher temperatures and humidity, and their blood-sugar was reduced in quantity. We have here an objective illustration of the enfeebling effects of hot, moist climates, which are familiar as subjective experiences.

THE *Bul. Imp. Acad. Sci.* (Petrograd, March, 1915) contains an article by A. A. Richter and E. M.

Digitized by Google

Kollegorsky describing a series of experiments on the mechanism of photosynthesis by means of a luminescent bacterium (*Photobacterium italicum*). Taking as the subject of their experiments two plants of strongly contrasted habits, *Aspidistra elatior* and *Bambusa verticillata*, they give the following summary of the results of their researches:—(1) The working out of a new method of the quantitative study of photosynthesis by the aid of luminescent bacteria. (2) It is established that the luminous intensity indispensable for the decomposition of carbonic acid is the same for plants which vary ecologically. (3) It is shown that the luminous intensity effecting the liberation of oxygen in photosynthesis may be in the case of plants possessing special light-collecting apparatus much lower than for those not so provided.

MUCH valuable meteorological and magnetical work is being done at Hongkong, and the report of the director, Mr. T. F. Claxton, has just reached this country. Continuous photographic records are being maintained showing the variations of barometric pressure and temperature, and there are daily automatic records of the direction and velocity of the wind, the amount of rain, duration of sunshine, and the relative humidity of the air. Eye observations of many of the elements are also made each hour. Attention is directed to the defect of wind velocity which has been noticed for several years past, and this has hitherto been attributed to instrumental rather than climatic causes. The decrease has occurred more or less steadily from 1884 to 1915. A similar defect in the wind velocity has been noticed at the Royal Alfred Observatory, Mauritius. The director of the Mauritius Observatory, in a recent report, remarks: "There is now reason to believe that the low velocities during the years 1901–11 are almost entirely climatic, and due probably to a periodic oscillation in this element." At Hongkong the decrease in the mean velocity of the wind is said to be far greater than the secular variations in any other element, and must, in the opinion of the director, at least in part, be attributed to instrumental causes.

THE Journal of the Franklin Institute for August contains a paper by Prof. Kennelly and Messrs. Achard and Dana, of the Massachusetts Institute of Technology, dealing with the increase of the resistance of standard forms of track and contact rails when the current through them is an alternating instead of a direct one. The currents used were sinusoidal of frequencies from 25 to 60 per second, and varied in root mean square values from 10 to 800 amperes. Both the alternating potentiometer method of comparing voltages down the rail and a manganin strip in series, and the dynamometer method of measuring the current and the active and reactive components of the voltage down the rail, were found satisfactory. The ratio of the resistances with alternating and direct currents increased with the magnitude of the currents to a maximum, at which it remained in most cases, but in a few cases it diminished again. The ratio, when a maximum, had values about 7 for track and 12 for contact rails at a frequency 25, and varied nearly as the square foot of the frequency. The best form of rail is discussed, and it is shown that theory reproduces the observations with a fair degree of accuracy.

WE have received from Mr. Oertling a copy of his recently issued catalogue of balances and weights. This firm claims that all its balances, etc., are, and always have been, manufactured in London. On comparison of the present list with that issued in 1909, we notice that with few exceptions all the balances listed seven years ago appear in the new catalogue; the prices, however, have increased in a proportion varying from 19 to 26 per cent., presumably owing to the general increase in cost of commodities and labour due to the war. Several balances designed especially for the Royal Arsenal, Woolwich, the Aircraft Factory, the Admiralty, and for explosives factories now appear for the first time. One of these is specially adapted for rapidity of weighing. Except in one item the weights are listed precisely as in the 1909 catalogue. The exception is that a cheap set has been introduced for school use. The increase in price of the sets of weights is not so large, varying from 11 to 20 per cent., except in one instance.

WE learn from the *Engineer* of September 1 that the Reclamation Service of the United States has recently finished at Elephant Butte, about twelve miles west of Engle, the dam which forms the keystone of its great water storage project in New Mexico. The work, which has been under construction since 1911, is designed with the object of providing water for irrigational purposes, by means of the storage of the flood waters of the Rio Grande, which are to be distributed at various points downstream, so that a total area of 185,000 acres will be brought under treatment. The district has a general elevation of 3700 ft. above sea-level; the climate is mild, and the temperature fairly equable throughout the year; the annual rainfall is about 10 in. It is thus a suitable location for husbandry, if the soil be adequately watered. The lake, or reservoir, which has been formed by damming the cañon of the Rio Grande at Elephant Butte, has, when full, a storage capacity of 862,200 million gallons, a surface area of 42,000 acres, a maximum length of 45 miles, a maximum depth of 193 ft. (the average is one-third of this), and a shore line of something above 200 miles. The dam contains 610,000 cubic yards of masonry, estimated to weigh about a million tons. It is not quite so imposing a structure as the two earlier dams built by the same service, but it is nevertheless a notable engineering achievement, and the outlay of about 1,000,000*l.* on the scheme will probably be considered but a moderate price to pay for the benefits which are expected to be derived from the undertaking.

MR. A. T. HOPWOOD writes to say that the display of aurora described by Mr. Denning in NATURE of August 3, was visible in Manchester about 11 p.m. (Summer Time) on the night of August 26.

ECONOMIC pamphlets on "The House-Fly as a Danger to Health," "The Louse and its Relation to Disease," and "Fleas as a Menace to Man and Domestic Animals," have already been published by the British Museum (Natural History), South Kensington. Three further pamphlets on, respectively, "Mosquitoes in Relation to Disease," "The Bed-Bug and its Relation to Disease," and "Ticks, etc., Injurious to Man," are in preparation.

## OUR ASTRONOMICAL COLUMN.

MEASUREMENT OF CLOSE SOLAR LINES.—As a preliminary to the determination of the wave-lengths of solar lines in international units, and in connection with the search for mutual influence between neighbouring lines, Dr. C. E. St. John and Miss Ware have made a careful study of the difficulties attending the precise measurement of closely adjacent lines (*Astrophysical Journal*, xliv., p. 15). Micrometric measurements were made by at least two observers upon a series of spectrograms representing the first five orders of

Digitized by Google

the 30-ft., and the first order of the 75-ft. spectrograph, and in the case of the closest pairs curves were also obtained with the registering photomicrometer; the separations derived by the latter process appeared to be least affected by accidental or systematic errors. The mean separations determined at Mount Wilson by three methods were systematically smaller than those indicated by Rowland's tables, the difference varying inversely as the separation. For six pairs, mean separation 0·274, the difference was +0·003; for eight pairs, mean separation 0·145, it was +0·008; and for eight other pairs, mean separation 0·075, it was +0·013. These differences are regarded as being probably due to errors in the Rowland values. The filar-micrometer values were found to vary with the width of the slit and the density of the spectrograms; whatever decreased the intensity of the space between the two components, as compared with the continuous spectrum outside, led to over-estimation of the interval. These results have evidently an important bearing upon recent attempts to detect effects due to anomalous dispersion.

The curious personal errors in the measurement of close lines have also been discussed from another point of view by H. H. Plaskett, in a paper entitled "The Psychology of Differential Measurements" (Journal R.A.S. Canada, June, 1916; NATURE, vol. xcvii., p. 451.)

SPECTRA AND ABSOLUTE MAGNITUDES OF STARS.—It has previously been shown by Adams that stars of small proper motion are relatively weaker in the more refrangible parts of the spectrum than stars of large proper motion, and that for stars of classes F to K this difference increases with advancing type. While the first result suggests a scattering of light in space, the second indicates that the absorption in the violet depends, in part at least, on the physical state of the star. This investigation has recently been extended at Mount Wilson by G. S. Monk, who has examined about 1200 plates of stellar spectra (*Astrophysical Journal*, vol. xliv., p. 45). The results are in general agreement with those of Adams, but show the effects to a less extent. All the density measures which could be so used were further discussed in relation to the absolute magnitudes of the stars, as determined by Adams on the basis of intensities of certain special lines. A relationship was thus indicated as existing between absolute magnitude and the relative weakness in the violet part of the spectra of stars having small proper motions, and it is concluded that the greater part of this effect is not due to absorption of light in space. It is thought probable that, with the aid of photographs specially taken for the purpose, the relative intensity of the violet part of the spectrum, together with spectral type, might be successfully employed to provide fairly accurate values of absolute magnitudes. An additional spectroscopic method of determining stellar distances is thus suggested.

OBSERVATIONS OF MINOR PLANETS IN FRANCE.—It is gratifying to find that in spite of difficulties caused by the war, the French observatories have been able to secure a large number of observations of minor planets. A useful summary of these observations, made during the year 1915, is given in the *Journal des Observateurs*, vol. i., No. 10. Although no new discoveries were made by French astronomers, an abundance of precise observations of about 120 known minor planets were obtained. About two-thirds of the observations were made at Algiers, on plates taken with the instrument employed for the photographic chart of the heavens. In addition, numerous ephemerides, in many cases constructed from corrected orbital elements, were issued by the Marseilles Observatory.

## THE MARITZBURG MEETING OF THE SOUTH AFRICAN ASSOCIATION.

THE fourteenth annual session of the South African Association for the Advancement of Science was held in Maritzburg, the capital of the Province of Natal, on July 3–8, under the presidency of Dr. Lawrence Crawford, professor of mathematics in the South African College, Capetown. The meetings of the sections took place in what used to be the Natal Houses of Parliament, the buildings of which are now the abode of the Natal Provincial Council. On the afternoon of the opening day of the session the president and members of the association were officially welcomed by the Mayor and Corporation of Maritzburg, and in the evening his worship gave a reception in the Town Hall, after which the president took the chair and delivered his address.

About eighty-five papers were read in the four sections into which the association is usually divided, and summaries of a few of these are given below.

Prof. John Orr, who will preside over the 1917 session of the association, which is to be held at Stellenbosch, Cape Province, was president of Section A at Maritzburg, and his presidential address, which was profusely illustrated by means of lantern slides, was largely a review of the progress of engineering science in South Africa of late years, particularly in connection with mining operations on the Rand.

The presidential address in Section B was given by Prof. J. A. Wilkinson, professor of chemistry in the South African School of Mines and Technology, Johannesburg. He laid stress on the fact that South Africa continues to exist on its rich stock of raw materials—its exports, in addition to the raw products of agriculture, being chiefly metals, crude and unrefined, and uncut diamonds. He devoted his address to urging the need of organising the development of chemical industry and research in the widest sense of those terms. He deplored the existence of the popular impression that the duties of the chemist and the pharmacist are identical, and to this cause he ascribed the fact that South African products were not up to the standard of imported goods. In conclusion, he submitted details of a scheme for organising chemical research in South Africa upon sound lines, and urged that this organisation should be undertaken without delay.

Mr. I. B. Pole Evans, chief of the division of botany in the Union Department of Agriculture, was president of Section C. His presidential address took the form of a sketch of the rise and development of mycology in South Africa. Persoon, the father of the science of mycology, he pointed out, was a South African, having been born at the Cape in 1755, and some of the earliest references to Cape fungi are in his "Synopsis methodica fungorum," published in 1801. During the course of his address Mr. Pole Evans incidentally referred to his own appointment as mycologist to the Transvaal Government in 1905. He could not be expected to know that some years previously the Cape Government, too, had put a sum of money on the Estimates for the salary of a mycologist, but so much sport was made of the item in the Cape Parliament that it was hurriedly withdrawn. "The ignorance of the subject and the vague notions that people have about fungi are," said Mr. Pole Evans, "due chiefly to the fact that most of them are microscopic, and consequently cannot easily be conceived by those unfamiliar with the life of the unseen world."

Section D was presided over by Mr. M. S. Evans, who took as the subject of his address a survey of the past and present relations of the European and Bantu

Digitized by Google

races in Natal and the surrounding districts. He recalled the conditions of native life as they were when he first landed in South Africa about forty years ago. The influence of the white man had been in favour of the Bantu people, for whom it was then an idyllic time. In 1886 came the great discovery which altered the whole social and economic position, not entirely to the native's advantage. Since then two waves of cattle disease—first rinderpest and then East Coast fever—swept across the territories, and an economically free people with considerable assets has been transformed into a community of debtors. Now education has come, and along with it unrest, the old life no longer satisfying, and so capacity has brought about a hunger to take a higher position. The question is now one which calls for scientific treatment, for investigation, for careful generalisation, and for application to the welfare of mankind.

Of the papers read at the various sectional meetings little can be said here. In Section A there were mathematical papers by Sir Thomas Muir and Prof. Roseveare, and papers on industrial development by Prof. Orr and Mr. Kenneth Austin; but those which attracted most popular notice were two short ones on daylight saving and the metric system respectively by Mr. R. T. A. Innes, of the Union Observatory. The principles advocated in both these papers were unanimously affirmed by Sections A and D meeting jointly, and resolutions were passed urging the Union Government to adopt those principles.

In Section B a highly important compilation of analytical figures from various sources was submitted by Prof. M. Rindl, of Grey University College, Bloemfontein, in a paper on the medicinal springs of South Africa. Dr. C. F. Juritz read two papers: one on the wheat soils of the Alexandria district, a tract of country where wheat once flourished, but in which there has been great deterioration during recent years; another on experiments with sugar beet in South Africa, bringing up to date the record of investigations which had already formed the subject of two previous papers by the author. Dr. A. L. du Toit contributed a paper on the occurrence of molybdenum in Natal, where the metal is present in the unusual condition of an impregnation in coarse sandstone of Upper Triassic age. In a paper on Fischer's synthesis of tanning materials the president of the section hinted at the possibility of synthesised depsides proving a formidable rival to the Natal wattle industry.

Section C had a very large number of papers, and only very few of these can be so much as mentioned here. Mr. J. L. Henkel, Conservator of Forests for the Natal Province, contributed three papers on different phases of forestry in Natal, and there were other papers on the subject by Mr. T. R. Sim, who also read a paper on wattle growing, another paper on the entomological aspect of the latter subject being read by Mr. C. B. Hardenberg. Four papers, having as their respective subjects the mealy bug, the Argentine ant, the house fly, and the cultivation of strains of beneficial insects, were submitted by Mr. C. W. Mally. Dr. Ethel Doidge contributed three important papers on bacterial diseases in citrus and pear blossom and on citrus canker. Mr. F. Vaughan Kirby read a paper on game protection in Zululand, while Mr. D. T. Mitchell discussed the association of game in Zululand with tsetse-fly disease. Mr. W. R. Tucker gave an account of the progress of the Natal sugar industry, and Mr. W. H. Scherffius discussed the cotton-growing industry.

Section D, too, was fully supplied with papers, so much so, indeed, that next year will see it divided into two sections, the council having decided to establish a new section, E, specially for native affairs, a subject which has engrossed much attention in Section D during the last three sessions. Two papers in this section by the Rev. Noel Roberts, illustrated with lantern views, on "Rock Paintings in the Northern Transvaal" and on "Bantu Methods of Divination," were both highly appreciated. The Rev. W. A. Norton read an informative paper on Bantu movements in Africa, illustrated by African place-names. Another paper of similar character was read by the Rev. John R. L. Kingon on the place-names of the Tsolo District. One of the most important papers read in Section D was delivered by the Rev. B. P. J. Marchand, and gave an account of the history and operations of the labour colony at Kakamas, on the banks of the Orange River. A valuable paper entitled "The Relation of Production to Consumption," by Mr. P. J. du Toit, Under Secretary for Agriculture, indicated the growth of South African farming industries, and advocated, as channels for constant progress, the increase of the European population, the development of fresh markets, and the educational and social advancement of the natives. Dr. Loram read a paper comparing the mentality of natives and Europeans in view of the theory of arrested development of the former. The Rev. A. T. Bryant gave two papers on the religion of the Zulu, and the concluding paper of the session was read by the Rev. J. R. L. Kingon on native education. Mr. Kingon said that this subject was one of supreme concern to the South African nation. Originally, the deliberate policy of the Imperial Government had been to provide native education as an insurance against Kaffir wars, but to-day the problem is chiefly economic and moral, and on both grounds he urged that the argument against native education is erroneous and unsound.

During the session two evening discourses were delivered, one at Maritzburg by Mr. C. P. Lounsbury, chief entomologist of the Union, on "Scale Insects and their Travels," and the other at Durban by Mr. R. T. A. Innes, Union astronomer, on "Astronomy."

On the first evening of the session, after the presidential address, the president presented to Mr. T. R. Sim, in recognition of his botanical researches, an award of 50*l.* and the South Africa medal for achievement and promise in scientific research, the fund for the annual presentation of which was raised by the British Association during its visit to South Africa in 1905. C. F. J.

## *ECONOMIC HISTORY OF THE UNITED STATES.*[1]

IN 1904 work was commenced upon an extended study of the economic history of the United States, under the auspices of the Department of Economics and Sociology of the Carnegie Institution of Washington. The subject-matter of this study was divided into twelve departments, and the two volumes before us represent the contribution to learning of the Department of Domestic and Foreign Commerce. They include six parts, dealing respectively with "American Commerce to 1789," "The International Commerce of the United States," "The Coastwise Trade," "The Foreign Trade of the United States since 1789," "American Fisheries," and "Government Aid and Commercial Policy," which are based, in part, upon monographs, some of which have not been published. Vol. ii. contains a classified bibliography which runs to 24 pp., and vol. i. gives 10 pp. to notes and a bibliography concerning American

[1] "History of Domestic and Foreign Commerce of the United States." Vol. i. By E. R. Johnson, T. W. Van Metre, G. G. Huebner, and D. S. Hanchett. Pp. xv+363. Vol. ii. Pp. ix+398. (Washington: Carnegie Institution, 1915.)

Digitized by Google

Colonial commerce; there are three important railway and three useful fishery maps.

On the whole, the work achieves an object of notable importance—a comprehensive summary of one department of American history. There has been a development in time, but the more important changes have been spatial, so that the underlying unity of the work is geographical rather than historical; spread over an extensive area, the people have always tended towards sectional interests, and the chronological sequence of events necessarily depends upon a continuous adjustment to new topographical conditions. In the earlier periods the exchanges were triangular in character; at first, from the north-eastern coastlands ships carried produce to the West Indies; the goods were, practically, exchanged for sugar, which went to Great Britain, and were there exchanged for British manufactured products to be sent to Boston; later, when the Middle West became populous, farm produce from the Ohio districts went down the Mississippi, was exchanged for cotton, which was sent coastwise to New York, and was there exchanged for manufactured goods, which went west to the Ohio.

The gradual substitution of direct trading based upon increased facilities of ship, canal, and railway, upon increased divergence of fundamental interest as the several areas confined attention to one or other definite form of production, and upon the increased quantity of coin and coin equivalent in the country, is resolved into a commentary upon the steady development of the natural resources of the United States. Tobacco and cotton exports from the plantation States, direct trade with the West Indies (which was always of paramount importance), and direct trade, at a later date, with the Far East, gradually gave the United States the largest mercantile fleet in the world, and despite piracy and privateering, this predominance was maintained until the substitution of iron for timber in the construction of the hulls of ships. The story of the limitation of the fisheries, and of the decline of the whale fishery, helps to explain the smallness of the United States marine, both commercial and naval, at the present day.

The facts for the years 1860, 1880, and 1900 show that the production of maize, wheat, oats, and butter was at least trebled; coal production advanced from 13 to 241 million tons annually, petroleum from a half to 64 million barrels; the numbers of wage-earners engaged in manufacturing increased from 1¼ to 5¼ millions, and the manufactured products increased from 377 to 2600 million pounds sterling.

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

THE extension of the London (Royal Free Hospital) School of Medicine for Women at Hunter Street, Brunswick Square, W.C., will be opened by H.M. the Queen on Monday, October 2, at 3 p.m.

BY the death, on September 1, of Mrs. William Jackson, widow of Mr. William Jackson, of Thorngrove, Aberdeen, a large sum becomes available for the founding of a chair of engineering in the University of Aberdeen.

ARRANGEMENTS have been made by the Cheshire County Council Education Committee with the authorities of McGill University, Montreal, which will permit of 60*l*., in connection respectively with the Royal School of Mines and Armstrong College, Newcastle-upon-Tyne. The former scholarship will be known as the "Richardson," and the latter, a correspondent informs us, as the "Cameron-Swan," and not the "Cameron," as stated in our note.

THE syllabuses of classes which begin at the Sir John Cass Technical Institute, Aldgate, on September 25 has now been issued. The courses of instruction are specially concerned with the technical training of persons engaged in chemical, metallurgical, and electrical industries. In addition, facilities are offered for special investigation and research. We notice that the curriculum in connection with the fermentation industries includes courses in brewing and malting and the microbiology of the fermentation industries. In the metallurgy department advanced courses are provided on gold, silver, and allied metals, on metallography and pyrometry, and other important technical subjects.

AN abridged calendar for the forthcoming session of the London School of Economics and Political Science (University of London) has been issued. One of the objects of the school is to supply liberal courses of education specially adapted to the needs of persons taking up any kind of administration, such as the service of any Government or local authority, or the higher branches of commerce and industry. Courses of study are arranged also for students desiring to graduate at the University of London in the faculty of economics. The school is provided with a research department in which the methods of utilising great libraries and collections of material are explained and hints are given in the prosecution of research. The time-tables of lectures and classes printed in the calendar are comprehensive and exhaustive, and the list of lecturers includes the names of many distinguished authorities.

THE new session of the Battersea Polytechnic begins on September 19. In the day technical college, courses have been arranged in civil, electrical, motor, and chemical engineering, and full preparation for degrees in science at the University of London. The department of hygiene and physiology provides training for women sanitary inspectors and health visitors. Full evening courses will be held in a great variety of subjects in science, technology, and commerce. Special classes for the training of men and women munition workers are held, and the manufacture of munitions for the Admiralty is undertaken. At the request of the War Office, a full-time course in engineering for men of the Royal Flying Corps has been arranged. Red Cross classes for women in the subjects of first aid, home nursing, cookery, and laundry work are also held. In addition, the members of the chemistry department have been engaged on the preparation of chemical substances for the War Office, and the staff of the physics department has assisted in the testing of optical instruments for the Ministry of Munitions.

rocks.—M. **Friedmann**: The vortices in a liquid at variable temperature.—L. **Hartmann**: The determination of the mechanical equivalent of heat by the method of Hirn. It is shown that the hypothesis which forms the basis of the determination of Hirn is not confirmed by experiment.—C. **Camichel**: The amplitude of the odd harmonics in the strokes of a hydraulic ram.—G. A. **Le Roy**: A reagent for free chlorine in drinking water. The amount of free chlorine in drinking water which has been purified by means of hypochlorites is at present controlled by the well-known iodide of starch reaction. The new reagent suggested, which has a higher sensibility than the iodide of starch, is the chlorohydrate of hexamethylparaminotriphenylmethane. The violet colour is formed immediately, and its intensity is proportional to the amount of free chlorine present. Water containing only three hundred millionths of chlorine gives a visible reaction with the new reagent; about three times this quantity is necessary to show the iodide of starch reaction. Details for the preparation and use of the reagent are given.

CAPE TOWN.

**Royal Society of South Africa**, July 19.—Dr. L. Péringuey, president, in the chair.—E. J. **Goddard**: *Pelodrilus africanus*, a new Haplotaxid from South Africa. The species here described constitutes the first representative of the family Haplotaxidæ recorded from South Africa. Of the two genera included within this family, one—Haplotaxis—is represented by fresh-water species in Europe, North America, and New Zealand, while the remaining genus—Pelodrilus—is represented in New Zealand by a species inhabiting damp earth. The African species is to be included in the latter genus. The specimens were obtained in mud on Sneeuw Kop, near Wellington, Cape Province, at an elevation of 5000 ft. above sea-level. The length varies from 20 to 40 mm.—Paul A. van der **Bijl**: Note on *Polysaccum crassipes*, a common fungus in Eucalyptus plantations around Pretoria. *Polysaccum crassipes* is so common in Eucalyptus plantations around Pretoria that it appeared interesting to determine in what relation it stood to the Eucalypti. The investigation was begun at the Botanical Laboratories, Pretoria, and afterwards concluded at the Natal Herbarium, Durban. The morphology of the fungus is briefly dealt with and followed by suggestions which indicate that the relation between the fungus and host is one of symbiosis.

CALCUTTA.

**Asiatic Society of Bengal**, August 2.—Dr. N. **Annandale**: Zoological results of a tour in the Far East. I., The Mollusca of Lake Biwa, Japan. Lake Biwa, as might be expected from its geographical position and from what is known of the fauna of Japan generally, seems to be, so far as the Mollusca are concerned, the meeting-place of two lines of migration, one coming from the north, the other from the south.

## Raphael Meldola: Reminiscences

**by those who knew him. With a Chronological List of his Publications (1869-1915).** Edited by JAMES MARCHANT. With a Prefac by the Right Hon. LORD MOULTON.

In addition to a biographical memoir by Sir Willia n A. Tilden, the volume contains tributes and reminiscences of this eminent scientist. Dr. M. O. Forster, Professors W. E. Dalby, W. J. Pope, E. G. Coker, A. G. Green, and Sir T. E. Thorpe, with the late Silvanus P. Thompson, speak of his work in chemistry.

His activities as naturalist and astronomer are dealt with by Professor E. B. Poulton, Sir Archibald Geikie, Sir F. C. Gould, Sir Alexander Pedler, Sir Norman Lockyer, and others. A valuable addition to the volume is the complete Bibliography of Professor Meldola's writings.

## THE BRITISH OXYGEN COMPANY LTD.

**Works** for the production of **Oxygen** and other gases in **London** (Westminster, Greenwich and Stratford), **Birmingham, Cardiff, Wolverhampton, Manchester, Birkenhead, Sheffield, Newcastle-on-Tyne, Glasgow,** and **Sydney, N.S.W.**

**The Company** was formed in 1886 as Brin's Oxygen Company to develop means for the production of Oxygen on an industrial scale.

**The Company** is not only the acknowledged pioneer of the Oxygen Industry, but possesses the largest organisation in the World for the production and distribution of that gas.

**The Company** also manufactures and supplies in cylinders, NITROGEN, HYDROGEN, CARBONIC ACID, and other gases.

**The Company** has developed an extensive engineering business, and has specialised in the design and manufacture of Plant for the production and separation of gases by liquefaction, electrolysis, and other methods.

**The Company** is the exclusive manufacturer in the United Kingdom of apparatus for metal cutting by Oxygen, and also manufactures well-known types of gas Regulators, Oxy-Acetylene and other blowpipes, and a large variety of apparatus for use with gas cylinders.

For illustrated price lists and full particulars application should be made to any of the Company's Works or to the Head Office, **Elverton Street, Westminster, S.W.**

**Some Features in**

## WATSON'S "VERSALIC" 1/12 in. OIL IMMERSION OBJECTIVE.

**It has no equal for Laboratory purposes, and is particularly designed for hot climates.**

**Mechanical Points.**
- The British Science Guild has recommended that Objectives should be sterilised before screwing home, to prevent growth of fungus, &c., in hot climates. This is done in the "Versalic" 1/8 in.
- The B.S. Guild also recommended that the mounting should be of a colour to make the Lens easily distinguishable. The "Versalic" 1/8 in. is finished black.
- In addition, the lenses are NOT set in their Cells with cement, which is apt to become unreliable, but all lenses are fixed with a metal bezel; they cannot therefore become disp'aced, the front lens cannot be "pushed in."

**Optical Points.**
- Working distance of exceptional length—the maximum that can be given with maintenance of immersion oil contact. Unusually flat field. Corrected for use on stained objects.
- Magnifying power is that of other 1/8 in. Lenses to which Laboratory workers are accustomed, viz. 1/8th in. It is a nominal 1/8 in. Definition is superb, and the Lens a pleasure to use.

**The Objective is British made. It is designed for the Bacteriologist. It is especially recommended for hot climates. It will stand continuous rough working.**

**PRICE £5. IMMEDIATE DELIVERY.**

WATSON'S MICROSCOPES are reliable and accurate. The demand exceeds the supply because their works are necessarily diverted to Optical Munitions. Inquiries are invited, and an approximate date for delivery will always be given.

*Send for Catalogues* { *MICROSCOPES and ACCESSORIES (No. 2)* / *MICROSCOPES for METALLURGY (No. 2)* / *PHOTOMICROGRAPHIC APPARATUS* / *MICROSCOPIC OBJECTS (No. 3)* } *Post free on request.*

# MACMILLAN & CO.'S NEW BOOKS.

***1916 ISSUE NOW READY.***

**The Statesman's Year-Book.** Statistical and Historical Annual of the States of the World for the Year 1916. Edited by **J. SCOTT KELTIE**, LL.D., assisted by **M. EPSTEIN**, M.A., Ph.D. With Maps. Crown 8vo. 10*s.* 6*d.* net.

*NATURE.*—"The 'Statesman's Year-Book' makes its ever-welcome appearance. The editors, Dr. Scott Keltie and Dr. Epstein, have been able to obtain much statistical information regarding the belligerent countries, and, in the case of Germany, to include facts and figures based upon the latest officially published information."

**Canada's Future: What She Offers after the War.** A Symposium of Official Opinion. Edited by **E. A. VICTOR.** Med. 8vo. 6*s.* net.

**Highways and Byways in Galloway & Carrick.** By the **Rev. C. H. DICK.** With Illustrations by HUGH THOMSON. Extra crown 8vo. 6*s.* net.

[*Highways and Byways Series.*

*COUNTRY LIFE.*—"Mr. Dick has written a fine, big, gossipy book about a remarkably interesting and romantic part of Scotland. . . . Needless to say, Mr. Hugh Thomson has acquitted himself with his usual distinction in the well chosen and painted illustrations."

**Discovery; or, The Spirit and Service of Science.** By **Professor R. A. GREGORY.** With 8 Plates. Crown 8vo. 5*s.* net.

*THE CHEMICAL NEWS.*—"It is difficult to restrain over-enthusiasm in writing a notice of this book. Time-worn epithets of praise, recommendations to purchase and read, would possibly give a false idea of its significance. Prof. Gregory has a real message for the world and a real gift in proclaiming it, and his book has appeared at a moment when the people appear to be ready to hear, to be convinced, and to act."

PART IV. JUST PUBLISHED.

**A Class-Book of Chemistry.** By **G. C. DONINGTON**, M.A., late Senior Chemistry Master, City of London School, Author of "Practical Exercises in Chemistry." Illustrated. Crown 8vo. Part I. 1*s.* 6*d.* Parts I. and II. 2*s.* 6*d.* Parts II. and III. 2*s.* 6*d.* Parts I.–III. 3*s.* 6*d.* Part IV. METALS. 2*s.*

**A Manual of Practical Physics.** By **H. E. HADLEY**, B.Sc., A.R.C.Sc., Principal of the School of Science, Kidderminster. Illustrated. Globe 8vo. 3*s.*

*THE SCHOOLMASTER.*—"The help to be derived from such a text-book is incalculable. To the lonely student it will come as a boon. Its exercises are workmanlike and searching, and its 265 pages are cheap at the price."

**A Text-Book of Practical Physics.** By **H. S. ALLEN**, M.A., D.Sc., Senior Lecturer in Physics, University of London, King's College, and **H. MOORE**, A.R.C.Sc., B.Sc., Lecturer in Physics, University of London, King's College. Extra crown 8vo. 8*s.* 6*d.* net. Also PART I. PROPERTIES OF MATTER. 3*s.* net. PARTS II., III., and IV. SOUND, LIGHT, AND HEAT. 3*s.* net. PARTS V. and VI. MAGNETISM AND ELECTRICITY. 3*s.* net.

*THE ELECTRICIAN.*—"To those interested in the elucidation of elementary physical principles the book will be exceedingly useful, and praise is due to the authors for producing so readable a book."

PARTS V.–VI. JUST PUBLISHED.

**Elements of Geometry.** By **S. BARNARD**, M.A., and **J. M. CHILD**, B.A., B.Sc. Parts V.–VI. 2*s.*

*** Previously published: Parts I. and II. 1*s.* 6*d.* Part III. 1*s.* Parts I.–III. 2*s.* 6*d.* Parts I.–IV. 3*s.* Part IV. 6*d.* Parts III. and IV. 1*s.* 6*d.* Parts IV. and V. 1*s.* 6*d.* Parts I.–VI. 4*s.* 6*d.*

PART II. JUST PUBLISHED.

**Practical Mathematics for Technical Students.** Part II. By **T. S. USHERWOOD**, B.Sc., Wh.Ex., A.M.I.Mech.E., and **C. J. A. TRIMBLE**, B.A. Crown 8vo. 7*s.* 6*d.*

*** Previously published: Part I. 3*s.* 6*d.*

*THE SCOTSMAN.*—"This part carries on the exposition systematically through advanced developments on utilitarian lines, with a special and skilled regard for the needs of students of engineering and other kinds of applied science. It gives particular attention to vectors, is well equipped with exercises, diagrams, examination questions, and mathematical tables, and is in all respects a thorough-going class-book for technical students."

## GLEW'S SCINTILLOSCOPE
(PATENT)

SHOWS a magnificent display of scintillations, showers of sparks, direct from the mineral Pitchblende, Radium, Polonium, Uranium, Thorium, or any radio-active substance, even an Incandescent Gas Mantle contains sufficient Thorium to excite the very sensitive screen of the Scintilloscope, which is far more sensitive than the Spinthariscope. The Scintilloscope rivals the most delicate Electroscope as a detector of Alpha rays.

The eye sees an inexhaustible shower of stars of white light, giving a very realistic idea of the ceaseless activity of these marvellous substances which are producing the terrific bombardment causing this beautiful display.

GLEW'S SCINTILLOSCOPE, Superior Lens, with Extra-sensitive Radium and Pitchblende Screens, giving brilliant effects. Complete, 7/6, Post free, U.K. Foreign Postage extra, weight 2 ounces.

Pieces of Pitchblende mineral, ground flat and polished, with Sensitive Screen attached, for use in Scintilloscope or with any strong pocket magnifier, from 7/6 each, according to size.

**F. HARRISON GLEW** (PATENTEE), **156 Clapham Road, London, S.W.**

EXAMPLES ONLY, with or without Answers, 2*s.* Or in Two Parts:—Part I., with or without Answers, 1*s.* 6*d.* Part II., with or without Answers, 2*s.* A KEY Complete, 10*s.* 6*d.* net. Or in Two Parts:—Part I., 4*s.* 6*d.* net. Part II., 6*s.* net.

## REVISION PAPERS IN ARITHMETIC.

By W. G. BORCHARDT, M.A., B.Sc.

Crown 8vo. 1*s.* 6*d.* With Answers, 2*s.* [*Shortly.*

This collection of Arithmetic Questions consists of One Hundred Papers, divided into seven sections, each paper containing seven Questions. In addition to these papers, there are miscellaneous sets of questions on Mensuration, Percentages, Stocks and Shares and Decimals, while the book concludes with 150 Miscellaneous Problems.

## A SCHOOL GEOMETRY.

**Presenting concisely, and in a logical and convenient sequence formal proofs of the main propositions of Elementary Geometry.**

By H. H. CHAMPION, M.A., and the Rev. J. A. C. LANE, M.A., Assistant Masters at Uppingham School. Crown 8vo, with numerous Diagrams. 3*s.* 6*d.*

## A COURSE OF GEOMETRY—THEORETICAL AND PRACTICAL.

**A class-book for Secondary and Technical Schools.**

By A. H. BELL, B.Sc., Director of Higher Education, Sheerness. Crown 8vo, with numerous Diagrams. 2*s.* 6*d.*

## SOLID GEOMETRY.

By R. S. HEATH, D.Sc., Professor of Mathematics and Vice-Principal of the University of Birmingham. Crown 8vo. 3*s.*

## A SYSTEMATIC COURSE OF PRACTICAL SCIENCE FOR SECONDARY AND OTHER SCHOOLS.

By ARTHUR W. MASON, B.Sc., B.A. (Lond.), Head Master of the Secondary School, Leiston, Suffolk.

Small Quarto. With numerous Diagrams.

The **chief aim** is to train the pupil in **scientific method** and to develop a feeling of responsibility and initiative, so as to make him realise that *he* has *something to do*, for the proper carrying out of the work.

**BOOK I. INTRODUCTORY PHYSICAL MEASUREMENTS.** Forming a First Year Course in Physics. 1*s.* 6*d.* net.

**BOOK II. EXPERIMENTAL HEAT.** Dealing with all those parts of HEAT usually taken in a school course up to the standard of the Matriculation and Senior Local Examinations. 2*s.* 6*d.* net.

## A MANUAL OF ELEMENTARY PRACTICAL CHEMISTRY FOR USE IN THE LABORATORY.

By P. W. OSCROFT, M.A., and R. P. SHEA, M.A., Masters at Uppingham School. Crown 8vo. With Diagrams. 2*s.*

## A THREE YEARS' COURSE OF PRACTICAL CHEMISTRY.

By GEORGE H. MARTIN, M.A., F.C.S., and ELLIS JONES, M.A., Science Masters, Bradford Grammar School. With an Introduction by Prof. COHEN, B.Sc., Ph.D. In Three Parts. Quarto. Sold separately. Parts I. and II. 1*s.* 6*d.* each. Part III. 2*s.*

# PUBLICATIONS OF CARNEGIE INSTITUTION of WASHINGTON

## CLASSICS OF INTERNATIONAL LAW.

This series will include the leading works on International Law, the republication of which has been undertaken principally on account of the difficulty of procuring the texts in convenient form for scientific study. The text of each author will be reproduced photographically, so as to lay the source before the reader without the mistakes which creep into a newly printed text. An Introduction will be prefixed to each work, giving the necessary biographical details concerning its author and stating the importance of the text and its place in International Law; tables of errata in the original will be added when necessary, and notes to clear up doubts and ambiguities or to correct mistakes in the text will be supplied. Each work will be accompanied by an English version made expressly for the series by a competent translator. Dr. James Brown Scott, member of the Institute of International Law, will supervise these publications as General Editor.

ZOUCHE, RICHARD: Juris et Judicii Fecialis, sive, Juris inter Gentes et Quæstionum de Eodem Explicatio. 2 vols. ... ... ... ... ... ... ... $4.00

I. Reproduction of the First Edition (1650), with portrait of Zouche. Introduction by T. E. Holland. 220 pp.

II. Translation of the Text, by J. L. Brierly. 203 pp.

AYALA, BALTHAZAR: De Jure et Officiis Bellicis et Disciplina Militari. 2 vols. ... ... ... ... ... $7.00

I. Reproduction of the Edition of 1582, with portrait of Ayala, Introduction by John Westlake, &c. 253 pp.

II. Translation of the Text, by John Pawley Bate. 261 pp.

VATTEL, E. DE: Le Droit des Gens. 3 vols. ... ... $8.00

I. Photographic Reproduction of Books I and II of the First Edition (1758), with Introduction by Albert de Lapradelle. 600 pp. Portrait of Vattel.

II. Photographic Reproduction of Books III and IV of the First Edition (1758). 375 pp.

III. Translation of Edition of 1758 (by Charles G. Fenwick), with translation (by G. D. Gregory) of Introduction by A. de Lapradelle. 486 pp.

RACHEL, SAMUEL: De Jure Naturæ et Gentium Dissertationes. 2 vols. ... ... ... ... ... $4.00

I. Reproduction of Edition of 1676, with portrait of Rachel, Introduction by L. von Bar, and List of Errata. 361 pp.

II. Translation of the Text, by J. P. Bate, with Index of Authors Cited. 255 pp.

TEXTOR, JOHANN WOLFGANG: Synopsis Juris Gentium. 2 vols. In press.

I. Reproduction of First Edition (1680), with portrait of Textor, Introduction by Ludwig von Bar, and List of Errata. 350 pp.

II. Translation of the Text, by John Pawley Bate, with Index of Authors Cited. 380 pp.

## THE SIR JOHN CASS TECHNICAL INSTITUTE,

JEWRY STREET, ALDGATE, E.C.

**EVENING CLASSES IN METALLURGY.**

Head of Department ..... C. O. BANNISTER, A.R.S.M., M.I.M.M., F.I.C.

Lecturer on Metallurgy ... G. PATCHIN, A.R.S.M.

Lecturer on Metal Testing... E. M. BOOTE.

Elementary, Intermediate, and Advanced Metallurgy forming a graded four years' curriculum. Special Courses on Assaying, Metallography (including Pyrometry), the Metallurgy of Gold and Silver, the Metallurgy of Iron and Steel, Heat Treatment of Metals and Alloys, Mechanical Testing of Metals and Alloys.

The courses are suited to the requirements of those engaged in Metallurgical Industries, Assay Laboratories, and to those intending to take up Metallurgical work in the Colonies.

The Laboratories are open for

**Advanced Practical Work and Research**

both in the afternoon and evening.

**New Session begins Monday, September 25.**

For details of the classes apply at the office of the Institute or by letter to the PRINCIPAL.

## THE SIR JOHN CASS TECHNICAL INSTITUTE,

JEWRY STREET, ALDGATE, E.C.

The following Special Courses of Instruction will be given during the Autumn Term, 1916:—

**THE THEORY AND APPLICATIONS OF MATHEMATICAL STATISTICS.**

**By E. C. SNOW, M.A., D.Sc.**

A course of 10 lectures on the modern mathematical methods of dealing with statistical data in social, educational, economic and medical problems, suitable to teachers and students of economics. Opportunity will be given to students to take up problems on their own account, and assistance and direction will be given for such work.

**Wednesdays, from 5.30 to 6.30 p.m.**

The first lecture of the course will be given on Wednesday, October 4, 1916.

**THE METHODS OF DIFFERENTIAL AND INTEGRAL CALCULUS AND THEIR APPLICATION TO CHEMICAL AND PHYSICAL PROBLEMS.**

**By R. S. WILLOWS, M.A., D.Sc.**

A course of 10 lectures for those engaged in Chemical and Electrical Industries and students of Physical Chemistry, in which the subject will be treated more as a means of Chemical and Physical investigation, rather than from the mathematician's standpoint.

The standard of mathematics required on joining the class will not go beyond an elementary knowledge of Algebra.

**Friday evenings, 7 to 8 p.m.**

The first lecture of the course will be given on Friday, October 6, 1916.

Detailed syllabus of the courses may be had upon application at the Office of the Institute, or by letter to the PRINCIPAL.

*NEW SESSION OPENS MONDAY, SEPTEMBER 25.*

HACKNEY INSTITUTE, Dalston Lane, N.E. (Mathematics, Chemistry, Physics.)

NORWOOD TECHNICAL INSTITUTE, Knight's Hill, West Norwood, S.E. (Mathematics, Chemistry, Physics, Botany.)

PADDINGTON TECHNICAL INSTITUTE, Saltram Crescent, W. (Mathematics, Physics, Chemistry, Botany.)

Full Prospectuses may be obtained on application to the Secretaries of the respective institutions.

JAMES BIRD,
*Clerk of the London County Council.*

London County Council Education Offices, Victoria Embankment, W.C., September, 1016.

**ENGINEERING AND TECHNICAL OPTICS.**

## NORTHAMPTON POLYTECHNIC INSTITUTE,

ST. JOHN STREET, LONDON, E.C.

**ENGINEERING DAY COLLEGE.**

Full Day Courses in the Theory and Practice of Civil, Mechanical, and Electrical Engineering will commence on Monday, October 2, 1916. The Courses in Civil and Mechanical Engineering include specialisation in Automobile and Aeronautical Engineering, and those in Electrical Engineering include specialisation in Radio-Telegraphy.

*Entrance Examination* on Tuesday and Wednesday, September 26 and 27, 1916. These courses include periods spent in commercial workshops, and extend over four years. They also prepare for the Degree of B.Sc. in Engineering at the University of London. Fees £15 or £11 per annum.

*Three Entrance Scholarships* of the value of £52 each will be offered for competition at the Entrance Examination in September, 1916.

**TECHNICAL OPTICS.**

Full and Part Time Courses in all branches of this important department of Applied Science will be given in specially equipped laboratories and lecture rooms. *An Aitchison Scholarship* (value £30) will be offered in this department at the Entrance Examination.

Full particulars as to fees, dates, &c., and all information respecting the work of the Institute, can be obtained at the Institute or on application to

R. MULLINEUX WALMSLEY, D.Sc., Principal.

**APPLICATIONS** are invited for the temporary post of ASSISTANT in BOTANY in University College, Reading, rendered vacant by the absence on war service of Mr. R. C. McLean, Lecturer in Botany. Further particulars may be obtained from the REGISTRAR.

**UNIVERSITY OF LONDON.**

**KING'S COLLEGE, AND KING'S COLLEGE FOR WOMEN.**

FACULTY OF SCIENCE.

In this Faculty a Course of Study in Science is provided suitable for general education or for the Examinations of the London and other Universities.

Students are admitted either as Regular or Occasional Students. Several valuable Scholarships and Prizes are offered.

The Laboratories of the College are open to post-Graduates and Research Students.

The following are the Departments under the charge of the various Professors, assisted by the Junior Staff:—

| | |
|---|---|
| Mathematics ... ... | Prof. S. A. F. WHITE, M.A.<br>Prof. J. W. NICHOLSON, M.A., D.Sc. |
| Physics ... ... ... | Prof. O. W. RICHARDSON, D.Sc., F.R.S. |
| Chemistry ... ... | Prof. H. JACKSON, F.I.C., F.C.S.<br>Prof. A. W. CROSSLEY, D.Sc., F.R.S. |
| Botany ... ... ... | Prof. W. B. BOTTOMLEY, Ph.D., F.L.S. |
| Zoology ... ... ... | Prof. ARTHUR DENDY, D.Sc., F.R.S. |
| Geology and Mineralogy | Dr. W. T. GORDON, F.R.S.E. |
| Physiology ... ... | Prof. W. D. HALLIBURTON, M.D., LL.D., F.R.S. |
| Psychology ... ... | Dr. W. BROWN, M.A., M.B. |

The next TERM begins WEDNESDAY, OCTOBER 4, 1916.

For particulars as to this and other Faculties of the College—Engineering, Medicine, Arts, Laws, and Theology—apply to the SECRETARY, King's College, Strand, W.C.

**EDINBURGH & EAST OF SCOTLAND COLLEGE OF AGRICULTURE.**

SESSION 1916–17.

The WINTER SESSION begins on TUESDAY, OCTOBER 10.

The DAY CLASSES, in conjunction with certain University Classes, provide full courses of instruction in Agriculture, Horticulture, and Forestry.

Full particulars of Courses and Classes, and also of Bursaries tenable at the College, are given in the Calendar, copies of which may be obtained on application.

All the College Courses are open to Women Students.

ALEXANDER M'CALLUM, M.A., LL.B.,
Director and Secretary.

OCT 13 1916

THURSDAY, SEPTEMBER 21, 1916.

## CALCULATIONS FOR FLYING MACHINES.

*The Design of Aeroplanes.* By Arthur W. Judge. Pp. viii+212. (London: Whittaker and Co., 1916.) Price 9s. net.

AEROPLANE stability is not the only subject in which progress has been retarded in the early stages of aviation. It is not so very long ago that Prof. Herbert Chatley read a paper on the calculation of the stresses in aeroplanes, and at the conclusion up jumped "Mr. I Don't Agree With You" and said he "didn't think" the results would be of any value. The consequence of this system is that a person who is really an inventive genius has to spend the whole of his time in fighting against the opposition and prejudice of people who "*don't think,*" and he can produce original work only when he can get a post-graduate student or assistant to do the whole working of the necessary details.

As a result of this retardation the literature dealing with the strength of the materials used in aeroplane construction and the stresses in their component parts is quite inadequate for the efficient development of aerial locomotion.

So far as this book deals with details of experimental statistics, it fills a distinct want, and it is sure to receive favourable reviews in our engineering journals. But a great deal of the subject-matter is nothing more or less than boiled-down mathematics, and the process of boiling down has in some instances been conducted in rather an amateurish way; moreover, the book contains statements that are certainly misleading, if not worse, for they cannot be correct if read as they stand.

In the first place a large amount of space is taken up in the appendices with tables for the conversion of units and things of that kind, but no tables are given for use in logarithmic calculations. Now it will be seen that almost all the formulæ quoted in the book, whether empirical or theoretical, involve products and powers rather than sums and differences, and for the efficient use of these formulæ a working knowledge of the use of logarithms is indispensable. The author may tell us that the class of mechanic for whom this book is written does not know how to use logarithms; if that be the case, the sooner he learns the better. He would then be spared an immense amount of time in turning over pages and pages of tables and possibly not finding what he wants at the end. The practice of mixing up tables of mere results of arithmetical operations with tables of experimental data cannot be too strongly deprecated.

The treatment of such matters as moments of inertia is on the whole fairly satisfactory, but it would be better if the author had stated the theorem of parallel axes *in words,* besides giving the formula on p. 113. Experience in teaching elementary students shows that it is very difficult to get them to interpret even the simplest formula in a verbal statement.

The graphic method for constructing a curve the area of which represents the first or second moment of a given plane curve about a given axis is very suitable for teaching purposes, though for actual working an alternative representation could be obtained more easily by the use of a cubical parabola.

In connection with the relative merits and demerits of monoplanes and biplanes, statements are made on p. 31 which are on the face of them at variance with elementary considerations of common sense. We are told that a monoplane possesses a lower head resistance, due to the absence of separate struts, ties, etc., and that it possesses relatively smaller moments of inertia about the axes of symmetry. But it is surely obvious that the use of superposed planes renders it possible to reduce both the framework and the span with the same lifting area. If Mr. Judge's statements are true of actual machines, it must be as the result of circumstances other than the difference between the one-decker and the two-decker type of wings, and this should be explained; otherwise the statements are calculated to mislead.

There must, however, be something much more seriously in error in the statement of the "Bird Flight Data" quoted from Dr. Magnan's conclusions on p. 33. In the seventh line we are told that the total length of a bird in centimetres is equal to the cube root of the total weight in grams; in other words, that the relation between length and weight is the same as in a cube of water. Further, the area of the body is equal to the square of its length. In the next formula but one we are told that the weight of the wings in grams is 197 times the total loaded machine weight in grams. After this follow statements that the chord of the wing at the centre is 2·36 times, the length of the tail 2·6 times, and the real length of the body 5·9 times the cube root of the weight, which has already been stated as equalling the total length of the bird!

While, therefore, the present book is to be welcomed as a step in the right direction, it will be seen that the subject still requires further revision. Had it not been for the discouragement which Prof. Chatley's early efforts received as the result of "discussions" consisting in expressions of premature opinions based upon insufficient data, we do not doubt that by now Mr. Judge would have been handling the subject on more strictly scientific lines. G. H. B.

## PALÆOLITHIC MAN.

*Men of the Old Stone Age: Their Environment, Life, and Art.* By Prof. H. F. Osborn. Second edition. Pp. xxvi+545. (London: G. Bell and Sons, Ltd., 1916.) Price 21s. net.

PROGRESS in the study of prehistoric man has been so remarkable during the last few years that the demand for a rapid succession of more

Digitized by Google

or less popular treatises on the subject is not surprising. Most of the original memoirs are in technical language in serials that are not generally accessible, and it is natural that critical summaries by those who have taken part in such research should be widely welcomed. The curiosity of the intelligent public, however, is so eager for satisfaction in many matters which are still beyond the pale of scientific knowledge that there is ever a temptation to make a book successful by pandering to this taste. Probabilities and possibilities which have been judiciously considered in scientific memoirs, and rightly used as tentative hypotheses, run the risk of being quoted as established facts; while unique, isolated discoveries tend to be treated as if they were sufficient for the absolute determination of their mutual relationships and could be used for definite conclusions.

We venture to think that Prof. H. F. Osborn has sadly failed to resist this temptation in his new handsome volume on the "Men of the Old Stone Age," which has reached a second edition in America within six months of its original publication. In every respect it is in strange contrast with such works as Huxley's well-known "Man's Place in Nature," which Prof. Osborn curiously omits both from his historical sketch and from his valuable bibliography of the subject. We are definitely told that modern geology "has firmly established eight subdivisions or stages of Pleistocene time—namely, four Glacial, three inter-Glacial, and one post-Glacial," which can be recognised in America as well as in Europe. We learn with equal certainty that Piltdown man is "four times as ancient as the final type of Neanderthal man," while Heidelberg man is nearly twice as ancient as the Piltdown man, "according to our estimates." The gravels in which Galley Hill man was found "are by no means of the geologic antiquity of 200,000 years assigned to them by Keith," but "lie within the estimates of post-Glacial time—namely, from 20,000 to 40,000 years." In fact, the dates of the successive stages in prehistoric man's progress are so exactly given and so often repeated that they cannot fail to deceive the unwary reader, who must feel especially impressed by their precision when he notes Prof. Osborn's warning that the odd 1900 years of the Christian era must be added to each statement when he desires to reckon time from the present day.

Prof. Osborn has, indeed, attempted with great labour to present a connected story which is distinctly premature, and will give the ordinary reader an exaggerated idea of the value of the conclusions already reached in prehistoric research. With the aid of several industrious compilers, whose services he acknowledges, he has produced a most useful and up-to-date compendium of the facts, with references to the original papers on which his statements are based. Each section is also most profusely and beautifully illustrated, often with original photographs which were made on a tour through France and Spain. We feel, however, that the collected materials have not been used with sufficient scientific discretion and adequate literary skill to produce a satisfying result. We would only add that for those to whom much of the text may prove difficult reading, the illustrations with their legends will still be a source of instruction and delight, while the excellent chapters on later Palæolithic art will be particularly appreciated. A. S. W.

## THE NATURAL HISTORY OF HAWAII.

*Natural History of Hawaii: Being an Account of the Hawaiian People, the Geology and Geography of the Islands, and the Native and Introduced Plants and Animals of the Group.* By Prof. W. A. Bryan. Pp. 596. (Honolulu: The *Hawaiian Gazette* Co., Ltd.; London: G. E. Stechert and Co., 1915.)

THE suspicion that is awakened by the somewhat typical "American" puff that Prof. W. A. Bryan allows himself in the preface to the "Natural History of Hawaii" is dissipated when the book itself is read, and the author is to be congratulated on having produced a book that is at the same time readable, useful, and trustworthy. It gives the reader a very good general idea of the geology, geography, flora, fauna, and ethnology of the group, and it will be of especial value to residents who take an interest in the local natural history. There is a very large number of photographs, some of which are on too small a scale to be of any real use, while the details in others are lost on account of ordinary photographic, instead of orthochromatic (or similar), plates having been used. The voluminous indices are of great practical use.

The section on the people is disappointing in some respects; for example, it is futile in a popular book to say that "North, South, and Middle America, as well as Papua, Malay, China, Japan, and India, have each in turn been declared the cradle" of the Polynesian race, as the uninformed will be led to suppose that any of these alternatives is possible. We know more on this subject than the author admits to be probable. In view of the recent investigations into the problems of Polynesian ethnology, Prof. Bryan might have alluded to Dr. H. Allen's "Study of Hawaiian Skulls" (*Trans. of Wagner Free Inst. of Sci.*, Phil., v., 1898, p. 1), where a dual element in the population is demonstrated, though the conclusions thereon are possibly erroneous.

In dealing with the flora and fauna the author never loses sight of the problems of distribution; thus not only are the characteristics of the seashore, lowlands, and mountains described, but the variation that occurs from island to island and the significance of this are duly noted. In the case of the land snails, for example, great variation may occur, not only in different valleys, but in parts of the same valley, so that the Hawaiian group is a famous field for the student of variations.

Another good feature of the book is the careful manner in which native species are distinguished

Digitized by Google

from introduced species. Those who read the early reports by Dr. Perkins, of the British Association Committee, will remember how rapidly the endemic insects were being replaced by foreigners which had been introduced accidentally; this book deals with a further phase of that sad drama. We all know how successful the Americans of the United States have been in dealing with the problems of economic entomology, and in Hawaii this experience has proved most beneficial, for not only have the enemies of pests been acclimatised, but in the importation of insects to combat the spread of the injurious Lantana we have, we are told, "the first example in the world of the introduction of insects to prevent the spread of a plant." If one more grumble may be permitted, we would like to express surprise that any scientific man should adopt the popular but erroneous spelling for coconut; but to avoid an unpleasant concluding sentence it may be pointed out that all through the book there are occasional references to the ethnological aspect of certain plants and animals which are of interest to the ethnologist.

## COLLOID-CHEMISTRY.

*A Handbook of Colloid-Chemistry. The Recognition of Colloids, and their General Physico-chemical Properties.* By Dr. Wolfgang Ostwald. Translated by Prof. M. H. Fischer. Pp. xii+278. (London: J. and A. Churchill.) Price 12*s.* 6*d.* net.

IT is stated in the preface that this book has passed through three large editions in Germany. We are inclined to think that such success was due more to the fact that it was first in the field as a general treatise upon a subject which was attracting widespread interest than to intrinsic merit. The ideas especially of the general theoretical portion are superficial, and the writing loose, words being mistaken for ideas. It is stated more than once, for instance, that the colloid state is independent of chemical composition. Taken literally, the statement is merely foolish. How foolish two examples will suffice to show. Azomethane, one of the most remarkable of colloid substances, loses its colloidal properties if a single hydrogen atom of its complex molecule is replaced by a halogen. Gold, silver, and platinum readily form colloidal solutions in solvents which contain a replaceable hydrogen atom, while the base metals form such solutions in hydroxyl-containing solvents. The author, however, does not really mean what he as multiphasic systems. This is an unfortunate use of the word "phase," which Gibbs defined as a portion of matter "uniform throughout, not only in chemical composition, but also in its physical state." Probably the last thing we can claim for portions of matter of microscopic, and especially ultramicroscopic, dimensions is that they are physically homogeneous throughout. The misuse of the word "component" on p. 36, where it is confused with "phase," is probably an error of translation.

The least satisfactory part of the book is the section on surface energy. Here the author, by a series of unsound analogies, introduces unnecessary confusion in a region which Gibbs, Rayleigh, and van der Waals had reduced to order. The part dealing with special properties of colloidal solutions, such as molecular weight, viscosity, osmotic pressure, etc., gives, on the whole, a clear account of the work which has been done.

## OUR BOOKSHELF.

*The Practical Principles of Plain Photo-micrography.* By George West. Pp. xii+145 +plates viii. (Dundee: University College, George West, 1916.) Price 4*s.* 6*d.* net.

In this book plain and practical directions are given for the preparation of photo-micrographs with the use of powers up to a ¼-inch objective. The author very rightly insists that the beginner should commence with low powers, and as he gains experience proceed step by step to the use of the higher powers. A feature of the book is its "common sense": the tyro is not bewildered by a mass of details and scores of chemicals and solutions, but just a few are chosen and fully described which the author has used and found suitable, and throughout directions are given for the adaptation of simple apparatus to the end in view.

After a few pages of general introduction the subjects of microscope and powers, illuminants, colour screens and camera are dealt with; then follow sections on photo-micrography with a landscape camera, without a camera, and with a vertical camera. Next the details of the making of a photo-micrograph from beginning to end are given in dialogue form in the Sandford and Merton style, a method of instruction which personally we do not care for, but which enables the author to give many "tips."

The book is illustrated with two plates showing arrangement of apparatus and six other plates, each with two figures, reproductions of photo-

Digitized by Google

The book is well printed and the reproduction of the plates excellent, the price is exceedingly moderate, and we can recommend the work as an excellent one for the beginner.

*Tunbridge Wells and Neighbourhood.* Edited by H. R. Knipe. Pp. 207. (Tunbridge Wells: Pelton, 1916.)

THIS volume is a welcome addition to the series of local surveys which owe their origin to the annual congress of the South-Eastern Union of Scientific Societies. The series was begun by the "Survey and Record of Woolwich and West Kent," which was published in commemoration of the twelfth congress of the Union, held at Woolwich in 1907; and later surveys have been issued in connection with the congresses held at St. Albans, Hampstead, and Bournemouth. The present volume makes a notable addition to the series, despite the fact that, owing to the war, it has been brought out under special difficulties.

The South-Eastern Union of Scientific Societies is heartily to be congratulated on these surveys. They are all of them confessedly provisional; but if they are made the basis of patient and continued work, and if they open out beyond the biological and archæological fields to the civic and sociological fields as well, they will mark a great step forward in the much-needed development of regional survey. Two lines of development readily suggest themselves: that each year all the affiliated societies in the area in which the annual congress of the Union is to meet should map out in good time the contributions already available for a local survey and the ground which still requires to be surveyed; and that, after the annual congress has met, further work should be organised and the results printed at intervals uniformly with the congress volume, and so be readily incorporated.

There is always an abundant demand for guide-books of the popular and familiar kinds, but we see no reason why many towns and districts should not gradually provide themselves and their visitors with regional surveys, progressively developing in scope, exhaustiveness, and accuracy, and forming guide-books of a higher and a more intelligent order. Mr. Knipe and his collaborators are to be heartily congratulated on having provided the first draft of such a guide-book for Tunbridge Wells and neighbourhood. C. H. G.

*Through South Westland. A Journey to the Haast and Mount Aspiring, New Zealand.* By A. Maud Moreland. Second Edition. Pp. xviii +222. (London and Melbourne, Christchurch, Wellington and Dunedin: Whitcombe and Tombs, Ltd., n.d.) Price 6s. net.

THIS entertaining description of a five weeks' riding tour in South Island, New Zealand, gives an excellent impression of the character of the country traversed and much information as to the kindly disposition of the inhabitants. Both the text and the beautiful photographs with which the volume is provided will interest students of the geography and natural history of New Zealand.

## LETTERS TO THE EDITOR.

*[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.]*

### Life Assurance Tables.

YOUR article in NATURE for July 6, pp. 383–4, quotes me correctly "that life assurance business has been based upon mortality tables which represented the expectation of life under the relatively unhealthy conditions which existed a half-century ago"; and then, a few sentences later, the article makes the above quotation credit me with saying that the mortality tables were *published* "a half-century ago"—which I did not say.

Your article explains that the mortality table published in 1901, now in use by the assurance companies (of Great Britain?), is based upon mortalities observed by sixty assurance companies under the relatively unhealthy conditions which existed during the thirty years 1863 to 1893—that is, from more than "a half-century ago" (fifty-three years) to twenty-three years ago, *an average of thirty-eight years ago.* It is within the last thirty-eight years that the great advances in preventive and curative medicine (excepting vaccination) have been made.

The American Experience Table was compiled by Homans in the year 1868, and was based chiefly upon the mortality data of the Mutual Life Insurance Company of New York. These data therefore represent the relatively unhealthy conditions which existed in a period of time averaging considerably more than "a half-century ago." As the writers of the article on life insurance in the last edition of the "Encyclopædia Britannica" (p. 666, second column) say, the American Experience Table "is now in wider use than any other for computing the premiums of American companies." It therefore seems that my sentence, quoted in the first paragraph, thoroughly respected the value of understatement. W. W. CAMPBELL.

Lick Observatory, August 7.

### Pre-Columbian Use of the Money-Cowrie in America.

IN NATURE of August 10 (p. 488) there was a notice of an article by Mr. C. B. Moore (published in the Journal of the Academy of Natural Science of Philadelphia, 2nd Ser., part ii., vol. xvi.) on the explorations of aboriginal sites in the Tennessee River valley, which raises the interesting question of the provenance of certain cowries found there. These are pronounced by Dr. H. A. Pilsbry, the well-known American conchologist, to be examples of the money-cowrie, *Cypraea moneta,* of Eastern Seas, and they have never been recorded before from an aboriginal mound in the United States. Nor has the species ever been recorded living on any of the shores of the Americas. To account for their presence in the Tennessee mound, Dr. W. H. Dall, another of America's leading conchologists, has suggested that the cowries "may have come off one of Columbus's own ships"!

In the Peabody Museum, Cambridge, Mass., is the dress of a Cree woman, collected by the Lewis and Clark Expedition, 1804–5, on which are four dozen cowries of the dwarf variety *atava* of *C. moneta* (see *American Anthropologist,* 1905, for picture).

Willoughby believes these cowries were sold to the Indians by the Hudson Bay Company in the late eighteenth or early nineteenth century.

Montgomery (Transactions of the Canadian Institute,

Digitized by Google

1910, ix. (1), No. 20, p. 7, pl. 4, f. 6) records and figures a cowrie found in the Serpent Mound, Ontario. It is a regular *C. moneta*, and it is suggested that "this is probably one from the Hudson Bay Company's stock."

But these suggestions entirely ignore the uses made of the cowrie in America. If Columbus and the Hudson Bay Company really introduced *C. moneta*, as these speculations demand, are we to assume that they also instructed the Indians in certain remarkable ceremonials practised with this shell in Africa, India, and China? Is there any reason for believing that Columbus was even aware of such uses, and if he were, that he should have had the foresight to take *C. moneta* with him, and have devoted the limited time he spent in America in teaching the natives some of the lesser-known elements of Indian and Chinese beliefs?

The money-cowrie is, and has been for centuries, a sacred object among the Ojibwa and Menomini Indians, and is made use of in initiation ceremonies of the Grand Medicine Society (see Hoffman, Bureau of Ethnology, 7th Annual Report, 1885–86 (1891), and 14th Annual Report, 1892–93 (1896); also NATURE, January 27, 1916, for abstract of paper by the writer).

The tradition among the Indians is that the original sacred shell came through a particular hero-god, who acted as intermediary between the Great Unknown and the Indians, and founded their Medicine Society.

The initiation ceremonies consist of much dancing and the shooting forward by the medicine men of their medicine bags containing the sacred cowries. Mystic powers are attributed to the shells, and it is firmly believed that if they be swallowed by the medicine man, all he is obliged to do to transfer his power to the medicine bag is to breathe on it, the mysterious power and influence being then transmitted by merely thrusting the bag towards the desired object or person. At initiation ceremonies the magic influence is shot at the candidate's breast, and the cowrie—the symbol of life—is supposed to enter his heart; he becomes unconscious and falls forward on his face. The chief medicine man then raises the candidate's head slightly from the ground, and a sacred cowrie drops from the candidate's mouth.

The same shells are used apparently at baptismal ceremonies of the Ojibwa (see Greenwood, "Curiosities of Savage Life"). There is the same dancing and shooting forward of the medicine bags, and after much facial contortion each medicine man spits out two shells.

The essential part of these ceremonies is the supposed death and survival of the candidate, and it is remarkable how closely the prevailing idea of the cowries being connected in some strange manner with resurrection and resuscitation agrees with the ancient Chinese belief as evidenced in the ceremonial use of money-cowries in obsequies of the dead. In pre-Christian and later times cowries were used in China, in association with rice, for stuffing the mouth of the dead. Wild rice, it might be added, also enters into the ritual of Ojibwa and Menomini ceremonies.

Manchester Museum. J. WILFRID JACKSON.

**Notice of Possible Suspension of the Rules of Nomenclature in the Cases of Holothuria, 1758, vs. Physalia, 1801, and Bohadschia, 1833, vs. Holothuria, 1791.**

IN accordance with the requirements prescribed by the International Congress of Zoology, notice to the zoological profession is hereby given that on or about October 1, 1917, the undersigned proposes to recommend to the International Commission on Zoological Nomenclature that the rules be suspended in the following cases:—

*Holothuria*, Linn., 1758 (type *physalis*), vs. *Physalia*, Lamarck, 1801 (type *pelagica*). The effect of suspension will be to retain *Physalia* as generic name for the Portuguese man-of-war.

*Bohadschia*, Jaeger, 1833, vs. *Holothuria*, Bruguière, 1791. The effect of suspension will be to retain *Holothuria* for the sea cucumbers.

The motion for suspension includes the following points:—

(1) Suspend the rules in the case of the generic names in question.

(2) Permanently reject *Holothuria*, 1758, type *physalis*.

(3) Validate *Physalia*, 1801, type *pelagica* (syn. *physalis*, 1758).

(4) Accept *Holothuria* as dating from Bruguière, 1791, despite the existence of *Holothuria*, 1758 (if rejected).

(5) Said suspension is not to be construed as invalidating any specific name.

The grounds for suspension will be:—(*a*) A strict application of the rules in these cases will result in greater confusion than uniformity, because (*b*) the cases involve a transfer of generic names, almost universally accepted in the sense given above since 1791 (for *Holothuria*) and since 1801 (for *Physalia*), to genera in other groups in connection with which they have been used by only a very few authors during more than 100 years.

The undersigned cordially invites zoologists to communicate, not later than September 1, 1917, to him or to any other member of the Commission, either their approval or disapproval of the proposed action.

C. W. STILES,
Secretary to Commission.

Office of Secretary to International Commission on Zoological Nomenclature, Smithsonian Institution, Washington, D.C.

## SCIENTIFIC AND INDUSTRIAL RESEARCH.

THE first report of the Advisory Council of the Committee of the Privy Council for Scientific and Industrial Research was published in full abstract in the issue of NATURE for September 7, and has probably already been read by all who are interested in this important matter. It will therefore be unnecessary to refer in detail to the contents of the report, but it is essential to consider it in its broad aspects and thoughtfully to estimate its bearing as a contribution to the subject of much discussion and contention in the past two years.

One feature of the report is the degree to which it repeats much that has been said and written by British scientific men, engineers, and practical manufacturers in the public discussions which have taken place on this subject during the past twenty-five months or more, but without carrying the matter forward by the prescription of practicable remedies for recognised defects. The arguments for and against various actions are weighed with an air of detachment which gives to it rather the character of an interesting essay than the authoritative decisions of a committee possessing executive power. The public has, without doubt, looked

Digitized by Google

forward to this first report of a committee of eminent scientific men for a masterly, comprehensive, and effectual treatment of the whole subject which would at least outline the strategy of the campaign. The report gives us, however, a more or less tentative discussion of the problem, and sums it up with the rather vague statement that its solution depends upon the largely increased supply of competent researchers, and, secondly, upon a hearty spirit of co-operation among all concerned.

As regards actual achievement, the Council has found that the conditions imposed by the war made it difficult to deal with the problem of assisting pure scientific research effectually, and therefore decided to give science in its applications to industry precedence. Here again, however, obstacles were encountered, and the Council has therefore limited its action to affording financial assistance to about twenty researches which were suggested or begun by engineering or professional societies. It has also expended about 6000*l.* in securing the assistance in certain researches of about forty persons not taken up with other war-work.

In addition to this, there have been established certain Standing Committees on mining, metallurgy, and engineering. A section of the report is occupied with the discussion of the attitude of industry to scientific research, but we think most experienced manufacturers would say that the analysis of the subject does not go deeply enough into the difficulties on the commercial side. The causes which have been at work in retarding or preventing the manufacturer from availing himself more completely of scientific research are very complex, and not by any means due to sheer lethargy or want of foresight. The problem of fostering and encouraging scientific industry is, in fact, a very much less simple one than that of promoting scientific research, although the two act and react on each other in several ways. There would be no difficulty, apart from the present abnormal war-time conditions, in finding men of ability to take up scientific research as a life-work provided only the inducements to it are made sufficiently great, any more than exists in the case of other professions. So long, however, as the pursuit of original scientific investigations remains a blind-alley occupation, or is only capable of being followed in the leisure moments of other work, such as teaching, or by men of independent means, so long will it fail to attract a large number of young men of ambition and ability to its pursuit.

What is required is the formulation of a scheme by which men who have decided or proved talents for pure scientific research can be enabled to devote themselves to it as a life-work with just as much opportunity for reasonable or exceptional emoluments as in other professions. It is said that if scientific abilities were properly utilised in industry such positions would be forthcoming, but having regard to present conditions we are in a vicious circle. If pure scientific research is of national importance, then it behoves the nation to make its pursuit possible as a profession apart from any connection with industry. It is, therefore, much to be regretted that the Council has not been able to formulate even in outline some more definite proposals with this end in view. The establishment of scholarships or temporary engagements at 150*l.* a year or so does not meet the case. There must be the prospect of such permanent and well-paid work as shall induce men of high abilities to take up research work as the business of their lives.

With regard to the relations of industry and science, the report does not furnish recommendations of any very definite character. It is realised by the Council that manufacturers and men of business have not any reluctance to avail themselves of scientific assistance or advice provided they can be shown that expenditure on it is an investment and not a mere speculation. Hesitation to embark on it is not always to be regarded as an indication of disbelief in its utility, but is determined very much by the scale of the business. A small concern, or one of moderate capitalisation, simply cannot afford to wait long for a return on an investment of capital. It must be certain of it within a limited time if it is to continue to exist at all. Moreover, of late years manufacturers have lived in an atmosphere darkened by the clouds of incessant contests with labour, and with the uncertainties arising from legislation directed rather by the interests of parties and politicians than by any serious attempts to support the staple industries of the country. Hence they have been compelled to take short views, and not launch out into enterprises which might bring them no appreciable return. Until these deep-seated difficulties are cleared away, it is therefore futile to reproach the individual manufacturer or manager with his backwardness in availing himself of scientific research.

The report supplies, however, a large amount of interesting information which shows that, under the pressure of circumstances, many trade associations, originally formed merely to fix prices, regulate production, or battle with labour, are now turning their attention to co-operative scientific inquiry as a means of relieving themselves of difficulties created by foreign monopolies of manufacture. In this effort it is probable also that the Advisory Council and its Standing Committees will perform the very useful function of being a clearing-house for ideas, suggestions, and inquiries, and act as guide, philosopher, and friend to these associations who are thus endeavouring to work out their own salvation. There is only one way in which the British manufacturer can meet the threatened post-war competition, and that is by standing shoulder to shoulder with his fellows against the common foe. Isolated they will be destroyed in detail, but as a phalanx they will prevail. The Advisory Council will, no doubt, fulfil a very important function in being a centre

Digitized by Google

to which confidential information and inquiries may be directed in the first efforts to establish and conduct that conjoint scientific work which such co-operation of kindred trades will require.

Turning, then, to that section of the report which deals with the sphere of the universities and technical colleges in relation to scientific research, we find the same absence of positive constructive suggestions for reform as in other portions of the report. The defects or deficiencies of our present conditions are pointed out, but the remedies for them only indicated in the most nebulous manner. It is stated with great truth that "the universities can and must be the main sources of research in pure science, the discoveries in which lie at the root of all practical and technical applications." But no definite recommendations are made as to how this output is to be increased.

It should be clearly recognised that effective research work of a high class demands a continuity of effort and time which it is in many cases almost impossible to obtain for university teachers. A man who has to drop his observations or experiments at a critical moment to go off and give a lecture or attend a committee or superintend a laboratory class is not placed under conditions in which the best work can be done. On the other hand, there are many men who are admirable and capable as teachers and as college administrators who have not the gifts of originality which make them shine as investigators. The only way out of this difficulty is to separate the functions more clearly. Every university should have research professorships and chairs, the occupants of which should have as their principal work to enlarge the bounds of knowledge in their particular subject.

The report does not furnish us with any definite proposals for the establishment of such research scholarships, fellowships, or professorships, but confines itself to the enunciation of broad and general aspirations in this respect. The universities will have suffered greatly by the close of the war in the loss of many of their most promising and talented students and teachers whose valuable lives have been given in the service of their country. We have to make provision for the careful cultivation of originality and research power in those who remain or return, and it would therefore have been much to the point if we could have found in this report a carefully-considered programme with this object in view. We think that many who study the report will feel disappointed that it does not contain more definite pronouncements of constructive policy in place of generalities. Much of it has the tone of an able article written for a leading monthly magazine rather than the enunciation of the matured conclusions and decisions on the part of a Government-appointed Committee recording the results of more than a year's consideration of this vital subject. Time presses, and our national position now demands vigorous and well-determined action rather than leisurely and academic discussion of our needs.

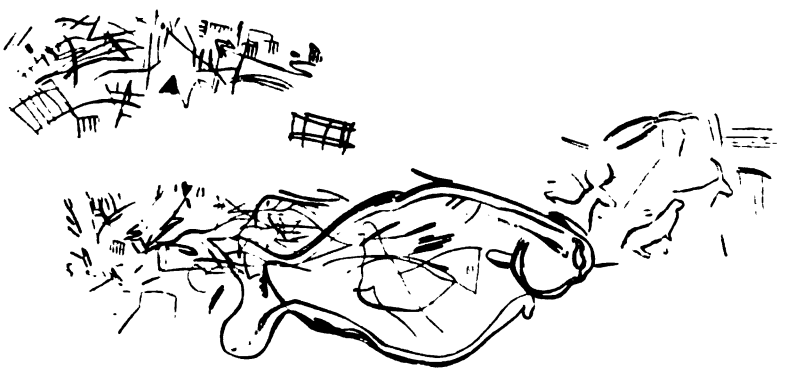
## THE ART OF THE CAVE.[1]

IN "La Pileta" a further considerable contribution is made to our knowledge of the Jurassic caves of South-west Europe by Abbé Breuil, in collaboration with Dr. Obermaier and Col. Willoughby Verner. The cave, which takes its name from the hill in which it is found, is, with its various corridors, recesses, and "galeries," more than usually complicated, and in fact at certain periods it provides accommodation for a stream and a lake. Wherever the cave opens out to form a chamber, wall paintings are to be seen, and it is these paintings which constitute the chief interest of the cave. The paintings comprise examples of four separate pictorial phases. The earliest are yellow in colour, and consist largely of serpentine forms with an occasional realistic figure of a goat, ox, or horse. The second series in chronological order is red in colour, and here, in addition to animal forms, are to be found various signs or symbols—recurrent dots, lines, spirals, ovoid figures, "claviformes" and "tectiformes." These are followed by a series drawn with charcoal, in which forms of animals naturalistically treated largely predominate, among them, be it noted, in considerable numbers the figures of fish—a new feature in parietal art, as the authors point out. With these are interspersed serpentine forms and schematic figures of animals. It is among these last figures that the authors believe they can recognise figures intended for human beings, and that an attempt has even been made to indicate the sex. The fourth and last series is purely schematic, and comprises geometrical figures with little or no zoomorphic or anthropomorphic suggestion. The vast majority of the figures are pectiniform, the number of teeth and the orientation of the backs of the combs exhibit-



Panneau No. 40, dit du grand Poisson. From "La Pileta."

[1] "La Pileta à Benaojan (Malaga) (Espagne)." Par l'Abbé H. Breuil, Dr. H. Obermaier, et Col. Willoughby Verner. Pp. 65+plates i–xxi. (Monaco: A. Chêne, 1915.)

Digitized by Google

ing a wide variation. In several cases the combs are combined to form composite figures. In the opinion of the authors the four phases represented extended over a long period, from Aurignacian to Neolithic times. The pictures are, although inferior in execution, closely related to those of Altamira, Niaux, and Font de Gaume, while the signs and symbols follow closely the rock engravings of Portuguese South-east Africa.

The most outstanding feature is the appearance of fish among the animal forms. The fish represented are of the Plaice or Brill family, and form the only instance so far known of fish painted on the walls of a cave, although engravings of fish have been reported from Pindal, Niaux, and "La Gorge d'Enfer." The book is admirably illustrated, and maintains in every way the high level which we have come to associate with the publications of the Institut de Paléontologie Humaine de Monaco. WILLIAM WRIGHT.

## *BACTERIOLOGICAL RESEARCH IN BOMBAY.*

THE report of the Bombay Bacteriological Laboratory for the year 1914, by Major W. Glen Liston, reached this country recently. The report is divided into two parts: (1) that dealing with plague work, and (2) that dealing with general preventive medicine. Statistics are furnished which tend to show that the uninoculated are attacked three times more frequently than the inoculated (against plague). One drawback to the use of plague vaccines is the severe reaction which follows, deterring others from undergoing the operation. It is now suggested, as results of experiments on rats and observations on man, that a small initial dose of 1–2 c.c. should be given, to be followed in a week by a second dose of 2–4 c.c. It appears that there are two other species of fleas of the genus Xenopsylla—viz., *X. brasiliensis* and *X. astia*—besides the originally known species *X. cheopis*, which, however, forms 80 per cent. of the three species concerned. Whether they all transmit plague is a question which must arise. The results of the examination of rats in the laboratory show that both in the case of *M. rattus* and *M. decumanus* there is a rise above the mean in the rate of infection in the latter half of January, whereas the rise above the mean in human plague mortality occurs in the first half of March. The fall below the mean occurs at the same time for both species of rats and for man—viz., in the first half of June. The summit of the infection for *M. rattus* calculated that the extermination of guinea worm would result in a net gain of 219 rupees per annum. Here, as elsewhere, sanitation always means a net cash gain in the end. The nature of rat-bite fever is unknown, but the fact that salvarsan rapidly cures it suggests a spirochæte origin. A "number of cases" came under observation; but why not state the actual number? The report, though short, contains much of interest and evidence of good, sound work.

J. W. W. S.

## *NOTES.*

WE record with deep regret the death on September 16, in his seventy-third year, of Sir Lauder Brunton, Bt., F.R.S., consulting physician to St. Bartholomew's Hospital, and of high distinction by his work and teaching in physiological medicine.

WE regret to see in the *Morning Post* the announcement of the death of Prof. Pierre Duhem, professor of theoretical physics in the University of Bordeaux, and the author of several works of wide interest on the history of natural philosophy and physical subjects.

ONE of the incidental effects of the European war upon America is the stimulus it has given to the adoption of the metric system. Very many American factories now turning out munitions for the Allies are working almost entirely in metric dimensions. Even locomotives are being manufactured in metres and millimetres. "The same thing, in all likelihood," says the New York *Evening Post*, "is taking place in England, which is furnishing munitions for Russia and other of her Allies."

A NEW YORK telegram announces the death on September 18, at sixty-six years of age, of Mr Seth Low, president of Columbia College from 1889 to 1901, during which period the college became Columbia University. Referring to his work for the university, the *Times* says: "He did much by his businesslike administration, his liberality (he personally contributed 200,000*l.* to the fund which enabled it to be removed to its magnificent site on Morningside Heights, New York City), and his especial interest in the department of political science."

THE Sociedad Argentina de Ciencias Naturales, of Buenos Aires, which issues the journal *Physis*, has arranged to hold meetings similar to those of the British Association, every two years, in one of the towns of the Argentine. No scientific assembly of this kind has hitherto been held in South America. The first meeting will be held at Tucuman in the last week of November next, in commemoration of the first centenary of the declaration of the independence of the Argentine Republic in 1816. Tucuman is the busiest and most populous town in the north of the republic. It possesses a university, a Museum of Natural History, of which Prof. M. Lillo is director, two

Zoology, Dr. E. L. Holmberg; V., General Biology, Anatomy, and Physiology, Prof. J. Nielsen; VI., Anthropology, M. J. B. Ambrosetti; VII., Physical and Chemical Sciences, Prof. E. H. Ducloux; VIII., Applied Natural Sciences, M. T. Amadeo; IX., Education in the Natural Sciences, Prof. V. Mercante. The general secretary of the Congress is Prof. M. Doello-Jurado, to whom communications should be addressed at rue Perú No. 222, Buenos Aires.

THE *Morning Post* of September 13 gives a brief account of a ship constructed of concrete with steel ribs, ordered by M. Broström, the Swedish Minister of Marine. The ship appears to be about one thousand tons in displacement, and resembles a large barge It is said that it is proposed to construct concrete ships of from 15,000 to 20,000 tons displacement, and a vessel of 3000 tons is now under construction. Our contemporary is not correct in describing this ship as the first stone vessel ever floated. Thus *Engineering* of June 14, 1912, gives a description and drawings of the first reinforced-concrete pontoon built in this country and used for sludge pumping on the Manchester Ship Canal. This vessel was constructed on the Hennebique system, designed by L. G. Mouchel and Partners, of Westminster, and was 100 ft. long by 28 ft. wide by 8·5 ft. deep; there were four transverse and two longitudinal bulkheads, and a complete installation of steam-pumping machinery. The first reinforced-cement boat appears to have been built by M. Lambot-Miravel in 1849, and was exhibited at the Exposition Universelle of 1855. An early example of ferro-concrete barge-building is the vessel completed in 1906 for M. Grancher, of Aveyron, in France, and employed regularly for sand dredging. Numerous other barges and pontoons of this type of construction have been built for use on the Tiber, Panama Canal, and elsewhere. There are, no doubt, possibilities in the development of ferro-concrete vessels, but we do not expect to hear in the near future of Transatlantic liners built on this plan.

IN the autumn of 1815, the year of Napoleon's final downfall, the Société helvétique des Sciences naturelles was founded at Geneva. It may, however, be called the offspring of two earlier societies, one representing the physical, the other the biological side of science, the older of which dated from 1791, and had thus survived the troubles inflicted by the French revolution. Small at first, it grew rapidly, and among the foreigners who attended its jubilee were Frankland and Tyndall. From the first it was a publishing society, and has now issued a fiftieth volume, in commemoration of its centenary, which was celebrated last year. This consists of reports from leading members of the society, which cover every branch of its work in the past and at the present time, together with short biographical notices of the workers themselves, many of them never to be forgotten by any scientific lovers of the Alps. The result is a very interesting volume, which will also have a permanent value in facilitating reference to the more important papers—and these are not few—which have been published by the Society. It has dealt with almost every branch of natural knowledge, for a mountain chain like the Alps propounds to the physical geologist not a few difficult problems, and as its climatic zones range from temperate to polar regions, it affords successive illustrations of their flora and fauna. The volume, in short, summarises the work of at least three generations of enthusiastic naturalists, workers at geology, physical geography, and meteorology, botany and zoology, past and present, and archæology (among whom we must not forget the earliest investigators of pile dwellings). One of the society's committees has also greatly aided in the systematic study of glaciers. It is interesting to learn that the idea of these having once extended far beyond their present limit occurred independently, in the year of the society's birth, to an engineer, Ignace Venetz, and to a chamois hunter of the Val de Bagnes named Perraudin.

THE *Electrician* was started as a weekly journal in 1861, when telegraphy was almost the only electrical industry. It came to an end in 1864, but was revived in 1878, at a time when the applications of electricity were becoming more numerous, and since then has always occupied a leading place amongst the electro-technical journals. In commemoration of the appearance of the 2000th number, which was issued on September 15, special articles are included in the number dealing with the development of the various branches of the electrical industry, and written by experts. As they touch on the principal events only, they are not too long for the general reader, and should prove of great value to the worker in one branch who wishes to know something of the history of those parts of the industry with which he is not immediately brought into contact. In addition to these historical articles there are others dealing with the present position of affairs in the industry and in the country which deserve careful consideration. Dr. Walmsley, as a teacher, urges the authorities to stop depleting the universities and technical colleges of the engineering and chemical students whose services will be so much needed by the country when the war is over. While on one hand the report of the Committee of the Privy Council for Scientific and Industrial Research expresses the pious hope that "voluntary efforts of manufacturers in friendly union" will succeed in raising the general level of manufacture in this country, on the other we find Mr. Swinburne putting forward the view that the manufacturer should be left to work out his problems in his own way.

IN the September issue of *Man* Prof. Seligman illustrates and describes a primitive form of reaping knife used by the sedentary Arab tribes of northern Kordofan. It can scarcely be called a sickle, consisting of an iron blade, more or less razor-shaped, and having at right angles at each end a small tang, which is thrust into a wooden handle. The blades are said to be made by the Arabised descendants of the pre-Arab iron-working Nuba, who still dwell on the hills which dot the plains of northern Kordofan. In reaping the dura the heads are cut off, with only a few inches of stalk, the stems being left in the ground until thoroughly dry, when they are pulled up and used for thatching, fencing, and other purposes. He remarks that this example may possibly indicate the purpose of a form of stone knife found in Europe in Neolithic times, as in the pile dwellings of Locras, whence comes the specimen now in the Sturge collection.

MR. W. H. D. LE SOUEF has reprinted from the Journal of the Royal Geographical Society of Australasia an interesting paper on "Aboriginals' Culinary Methods and Kitchen Middens." He remarks that, as regards food, little came amiss to them that was not absolutely poisonous. They did not eat any animal or bird they found dead unless they knew how it had been killed, and not even then unless it was fairly fresh, as they objected to meat that was much fly-blown. Slightly tainted meat did not trouble them much; they only cooked it a little more. Some of the mounds at which they used to cook their food are of large extent, as much as 100 ft. in diameter. Unfortunately many of these have been occupied by rabbits, and have thus suffered much injury. As

Digitized by Google

many of the kitchen middens along the coast are becoming eroded, the author suggests that a photographic record of them should be prepared before it is too late.

IN the Memoirs of the Connecticut Academy of Arts and Sciences (vol. v., 1916, pp. 1–96, plates i.–xxxix.) Dr. G. F. Eaton publishes an exhaustive report on the human skeletons from Indian graves at Machu Picchu, Peru, obtained by the Yale University Expedition of 1912. Most of the burials were in caves, and the mummies seem to have been placed sitting in the contracted position. A large proportion of the skeletons were imperfect, and Dr. Eaton suggests that many deficiencies were caused by accident when the mummies were temporarily removed from their burial places during festivals, in accordance with a well-known custom under the rule of the Incas. Of 164 skeletons collected, no fewer than 109 were certainly of females, while most of the male skeletons represented individuals of inferior physical development. Bronze and bone implements, objects of green chloritic schist, earthenware spindle-whors, and fabrics both of llama's wool and of vegetable fibre, besides a large collection of well-preserved pottery, are also described and figured. The rare articles of post-Columbian or European origin are to be regarded as having been introduced after the original burials.

SINCE the classic work of Gaudry on the late Miocene or early Pliocene mammals occurring in bone-beds at Pikermi, near Athens, discoveries of deposits containing similar mammalian remains have multiplied in eastern Europe. During recent years many have been made, especially in southern Russia, and various preliminary notices of them have appeared. Madame Marie Pavlow has now thoroughly investigated these discoveries, and published the results in a handsome memoir which forms the third and fourth livraisons of vol. xvii. of the *Nouveaux Mémoires* of the Imperial Society of Naturalists of Moscow. A description of the geological formations whence the fossils were obtained is appended by Prof. Alexis P. Pavlow. So far as known, the Russian fauna, with the usual preponderance of Hipparion, is remarkably like that of Pikermi, the only striking difference being the absence of the true Rhinoceros. After describing remains of giraffes, Madame Pavlow discusses a well-preserved skull of Palæotragus, which she maintains is an antelope, not a giraffe, as supposed by Forsyth Major. There are also remains of other well-known antelopes and gazelles, a few fragments of deer, and a fine skull of the large pig, *Sus erymanthius*. Several skulls of a hornless rhinoceros, Aceratherium, closely related to a species found at Maragha, in Persia, are important as making known several growth-stages. The numerous skulls and jaws of *Hipparion gracile* are also valuable for the same reason. Teeth of Mastodon, Dinotherium, and Orycteropus occur, and there are some fragments of Carnivora, including the skull of a large cat related to the American Miocene Pogonodon. Madame Pavlow has already made many welcome contributions to our knowledge of the newer Tertiary mammals of Russia, and she is to be congratulated on the manner in which she has presented the latest results of her researches.

BEFORE the war Russian men of science, and especially biologists, had to send a very considerable proportion of their writings abroad for publication, and witch and Dogiel are editing the *Russian Journal of Zoology*, Profs. Sewertzoff and Elpatiewsky the *Revue Zoologique Russe*, and Prof. Dogiel the *Archives Russes d'Anatomie, d'Histologie et d'Embryologie*. The first number of the latter has just appeared; it contains an article in English by A. Mamimov on "The Cultivation of Connective Tissue of Adult Mammals *in vitro*," and two memoirs in French, one by the editor on the structure of sensory nerve-endings in the beak and tongue of birds, and another by A. N. Sewertzoff on the morphology of the skull and head muscles of Cyclostomes. The excellence of these researches, no less than of the typography and illustrations, is a happy augury of the success of this new journal, on which Prof. Dogiel of Petrograd is to be heartily congratulated. It is of particular interest to note that, in spite of the enormous drain on the Imperial finances, the Minister of Public Instruction, Count Ignatiev, made the publication of this journal possible by a Government subsidy.

IN the Nouveaux Mémoires de la Société Impériale des Naturalistes de Moscou, M. G. A. Belogolovy records some very remarkable experiments on the development of the frog Pelobates. The experiments were undertaken with the view of throwing some light upon the factors that are concerned in bringing about the phenomena of recapitulation in ontogeny. Their significance from this point of view may be regarded as somewhat obscure, but at any rate they have yielded some very curious results, and perhaps it is not too much to say that they have opened up a new field in the domain of experimental embryology and pathology. The author's intention was to rear the embryos as parasites upon adults of the same species, instead of as free-living individuals in their normal aquatic environment. He introduced the eggs into the body-cavity of the adult through an incision in the body-wall, and found that they attached themselves to the surface of the various viscera, etc., and in the course of a few weeks developed into highly abnormal structures, sometimes permeated by blood capillaries apparently derived from the tissues of the adult, through which they derived their nutriment. These results will probably be of interest to pathologists rather than to embryologists, especially from the point of view of those engaged in cancer research. The necessary operation appears to be a very simple one, but the animals treated as hosts to the parasitic embryos remained alive but for a few months, and then only when kept in water. The memoir is well illustrated, the histological features of the parasites being represented in two very beautiful and elaborate coloured plates.

THE *Bull. Imp. Acad. Sci.* (Petrograd, May, 1916) contains the description of a new species, differing in many essentials from other species, of Helicoprion, *Helicoprion clerci*, so named in honour of Onisime Jegorovič Klerk (O. Clerc), president of the Ural Naturalists' Society. Accompanying the description are drawings in natural size of the five fragments found at Krasnoufimsk. So far only two species have been discovered in Russia—*Helicoprion bezsonovi* and another, hitherto undescribed, found by A. P. Ivanov in the Government of Moscow. The well-known American naturalist, C. R. Eastman, directed attention in 1905 to the instructiveness and unexpectedness of certain palæontological discoveries of recent years,

Digitized by Google

as an ichthyologist, focussed his attention on Helicoprion and allied forms, Edestus and others. Since then the interest in them has not waned, and the literature of the subject grows apace.

THREE valuable essays appear in the Proceedings of the Birmingham Natural History and Philosophical Society, vol. xiv., part 1. The first of these is by Mr. Leonard J. Wills, on "The Structure of the Lower Jaw of Triassic Labyrinthodonts." The author's investigations were based upon fragments of Labyrinthodont mandibles found in the Lower Keuper Sandstone of Bromsgrove, Worcestershire. The author comes to the conclusion that the Stegocephalian mandible helps to bridge over one of the gaps between the fishes and the reptiles. The jaw of the latter can be derived from the Stegocephalian mandible by a fusion or suppression of some of the elements, such as was probably taking place, even in Permian and Triassic times, in the case of the coronoid bones. The second concerns the geology of the eastern boundary fault of the South Staffordshire coalfield. The author, Mr. W. H. Foxall, describes the coal-beds, the Red beds, the Bunter Pebble beds, and the Glacial drift. The third, illustrated by numerous photographs and diagrams, is contributed by Prof. W. S. Boulton, who deals at length with the problems presented by an Esker near Kingswinford, South Staffordshire. The events recorded, the author believes, happened towards the close of "the Ice age, when the ice had ceased to advance; when, indeed, it was melting faster than it could be replenished from the northern Highlands, and the ice-front, in consequence, was slowly retreating northward."

SOME authoritative statement is required to discourage the popular belief that the heavy rains experienced this summer are connected with the bombardment in France and Flanders. In the Meteorological Office Circular, No. 3 (August 21) there is a note on the subject. Experiments to test this hypothesis have been made in Europe, America, Alaska, and Australia, but without result, and there is no evidence of any such influence. Furthermore, the energy of the heavy bombardment now proceeding, even if applied entirely to the removal of the heat required to produce rain, which it is not, would be inadequate for the purpose. Nor must the spells of brilliantly fine weather be forgotten. These occurred while the bombardment was proceeding.

IN an article in the *Geographical Review* for August, 1916 (vol. ii., No. 2), on the pirate coasts of the Mediterranean, Miss E. C. Semple points to the parallel between the hunting grounds of the German and Austrian submarines and those of the ancient and mediæval corsairs. Mediterranean piracy has recrudesced whenever maritime political control is relaxed, and certain localities determined by geographical conditions are the natural hunting-ground of the sea-robbers. The configuration of the basin has always compressed traffic into certain narrow routes. From these routes traffic is unable to deviate, as it can in the open ocean.

THE report for 1915 of the director of the Liverpool Observatory, Bidston, shows that the ordinary work of the observatory has been carried out during the past year, while progress has been made in at least one direction. Besides the Milne seismograph, a new instrument, designed by Mr. J. J. Shaw, has been erected to record the tilt produced by the oscillations of the tidal load in the neighbourhood, and is working with good results. The number of earthquakes registered during the year is 195. A small record was obtained of the Carlisle earthquake of October 2, the oscillations of which lasted for a quarter of an hour.

ATTENTION may be directed to the Monthly Record of Meteorological Observations, published by the Meteorological Service of Canada, of which we have received the number for March. It contains in a convenient form the complete meteorological data of some thirty stations in Canada, and also from Newfoundland and Bermuda. The publication contains two maps, one illustrating the total precipitation for the month, and the other the departure from the average temperature for the month. In addition to the stations providing detailed records, there are a large number for which only the monthly means and the extremes are given. There is, of course, a lack of data from the north of Canada. The monthly record contains no discussion of the data.

THE value of fique, the fibre of *Furcraea gigantea*, in Colombia is emphasised in a short article in Kew Bulletin No. 7 by Mr. M. T. Dawe, Director of Agriculture in Colombia. It is used for the soles of the native shoes or alpargatas, sacks, girths, ropes, matting, and even for roofing the houses. For the latter purpose the green leaves are used, and the article is illustrated by a photograph showing a cottage thatched with the leaves of fique. Hand-prepared fibre is sold in the Bogotá market at 6*d*. per lb., but by using modern machinery a profit of 19*l*. per ton might be expected if the fibre sold at its present wholesale price of 160 dollars per ton. On export with a selling price of 25*l*.–30*l*. per ton a profit of 5*l*.–10*l*. per ton should be realised.

WITH a view to the ultimate production of a portable dry storage cell, M. Charles Féry has, with the help of his pupil, M. E. Fournier, examined quantitatively the chemical changes which take place in the ordinary storage cell. His results will be found in the January number of the *Journal de Physique*. He finds that neither the simple theory of sulphation of both positive and negative plates first put forward by Gladstone and Tribe, nor the later theories involving the production of an unstable higher sulphate at the positive plate are in agreement with the measurements. In the first place, the amount of sulphuric acid which disappears during the discharge of the cell is half that required by the double sulphation theory. In the second place, the change of weight of the positive plate is much less than it should be according to that theory, and takes place in the opposite direction. His final conclusion is that the reactions which

## OUR ASTRONOMICAL COLUMN.

THE VARIABLE NEBULA IN CORONA AUSTRALIS.—A somewhat extended investigation of this remarkable object—N.G.C. 6729—has been made at Helwân with the Reynolds 30 in. reflector, and a brief account of the observations, with illustrations, has been given by J. H. Reynolds (*Monthly Notices*, R.A.S., vol. lxxvi., p. 645). The thirty-seven photographs taken during 1914 and 1915 clearly demonstrate that the nebula is variable in form as well as in brightness, and it seems probable that its variability is closely related to that of the variable star R Coronæ Australis, to which it appears to be attached. The appearance is such as might be expected if the nebulous matter was discharged from the star when at its maximum brightness and illuminated by it.

Further particulars are given by Mr. Knox Shaw, who took the photographs. The forms of the nebula can be classified into seven types, ranging from the first, in which the nebula is very bright and attached to the star, to the seventh, where the nebula is very faint and entirely detached. There is, however, no simple relation between the form of the nebula and the magnitude of the star; the nebula is brightest when the star is brightest, but is not always of the same form for a given magnitude of the star. It seems quite possible that the apparently imperfect correspondence between the variations of the nebula and those of the star may be caused by the presence of absorbing matter lying between them and the earth. If this absorbing matter were of varying thickness and in motion, it would naturally complicate the phenomena, but it is not suggested that this is the main cause of the variability.

PROPER MOTIONS BY THE BLINK-MICROSCOPE.—A further report on the use of the blink-microscope (see NATURE, vol. xcvi., pp. 237 and 438) in the detection and measurement of proper motions has been issued by Mr. Innes (Union Observatory Circular, No. 35). The greater part of the report refers to the comparison of eight astrographic plates taken at Greenwich, at intervals approximating to twenty years, and forty-three proper motions of stars ranging in magnitude from 7·1 to 13·5 are tabulated. As an indication of the rapidity of work by this method, Mr. Innes states that the investigation of the eight regions, including the identifications and reductions, occupied only twenty-four hours, although there was no attempt to make a record. Every pair of plates confirmed the impression that the vast majority of stars, bright and faint, are relatively fixed, and the measures were made on this assumption, the numerical work then being very slight. If plates are taken with a view to their ultimate examination by the blink-microscope, Mr. Innes considers that long exposures should be given, as crowded regions are a great advantage. Triple images are unnecessary, and double images are also superfluous if a third plate be available.

THE PERIOD OF U CEPHEI.—A discussion of Wendell's observations of this well-known eclipsing variable has been undertaken by Martha B. Shapley (*Astrophysical Journal*, vol. xliv., p. 51). The observations were made at Harvard during the years 1895–1912 with a polarising photometer, the total number of comparisons being 17,296; they have a special value because the instrument, method of observing, and comparison star were the same throughout this long period. As the light at minimum is constant for about two hours, Wendell observed mainly the steepest part of the ascending or descending branch, and in most cases the time at which the star was at a specified magnitude—say, 8.40—can be determined from the observations with an uncertainty of less than a minute. Variations in the mean phases of both steep branches are apparent, and there is evidence that the variation is not in the duration of minimum, nor due to variability of the comparison star, but a definite change in the light period. When all the observations since the time of discovery in 1880 are considered, it is evident that they are not satisfied either by Chandler's elements (1903) or by those of Wendell (1909). The latter serve best as a working formula at the present time, but would probably predict the minima too early. The variations are apparently very complex, and no attempt has yet been made to obtain an analytical expression for them. Wendell's formula is

$$\text{Min.} = \text{J.D. } 2407890{\cdot}3007 + 2{\cdot}4928840d.\ E$$

with zero phase at the midpoint of minimum light. The mean magnitude at minimum is 9·14, and at maximum 6·81.

## MR. JOHN ANGELL.

ON September 9 there passed away in the person of Mr. John Angell a figure notable in the educational world of Manchester. He was born in London in 1824, and in his early educational career was chemical assistant to Prof. Thos. Graham, F.R.S., professor of chemistry in University College, London, and was hon. secretary to the Birkbeck School Committee, whose school was the first established in Great Britain with the object of demonstrating both the desirability and the possibility of teaching soundly and rationally the elements of science as leading everyday subjects in the ordinary day school. In 1852 he accepted an appointment at the Salford Mechanics' Institute as head of the Boys' School established therein, and five years later became the organiser of the day and evening classes of the Manchester Mechanics' Institution, then established in a new and commodious building in that city, where he remained for twelve years, resigning his position in 1869 to accept the senior science mastership in the Manchester Grammar School, then under the vigorous direction of Mr. F. W. Walker, afterwards master of St. Paul's School, London. Mr. Angell remained at this post for eighteen years, during which period he greatly raised the reputation of the school by his energetic and intelligent teaching of science, especially in the subject of physics. He was an enthusiastic disciple of George Combe, whose teaching, as exhibited in his work, "The Constitution of Man," as he said, "completely revolutionised the course of my life." He was an ardent and enlightened exponent of the "Socratic" method of instruction, which he applied with much success in the courses he gave in chemistry, physics, and physiology to day and evening pupils during his career at the Manchester Mechanics' Institution. In 1868 the Institution was visited by a French Imperial Commission appointed to visit and report upon secondary education in England and Scotland. In its report it has nothing but praise for the methods of teaching in use. "If he selects a reagent, it is because some pupil suggested it; if he obtains a gas in his analysis, he has already caused his students to predict its nature. . . . 'My object,' as this excellent teacher told us, 'is to train the intellect through the study of science.'" His work as a teacher received the approval of such men as Drs. Joule and Angus Smith, and Profs. Clifton, Williamson, and Roscoe. He ceased his duties as a teacher in 1887, but continued his keen interest in scientific subjects in association with many of the literary and scientific societies of Manchester of which he was an active member almost to the day of his death at the ripe age of ninety-two. He was the author of many once widely used science text-books.

## AURORA AND MAGNETIC DISTURBANCES OF AUGUST 27, 1916.

WITH reference to the aurora reported by Mr. W. F. Denning at Bristol on August 27, between 2 and 4 a.m. G.M.T. (NATURE, August 31, p. 551), the Director of the Meteorological Office notes a report received from Mr. J. Ernest Grubb, observer at Seskin, near Carrick-on-Suir, Co. Waterford, Ireland, that aurora was visible there on the night of August 26 between 10.5 and 10.40 p.m. G.M.T. The greatest display noted by Mr. Grubb occurred about 10.25 p.m., when streamers from N.W. to N.N.E. stretched to within 20° or 30° of the zenith. The light was sufficiently brilliant to illuminate the interior of a room facing W.N.W.

At Eskdalemuir, Dumfriesshire, in spite of a cloudy sky, auroral glow in the N.W. was reported by the observer at 9 p.m. on August 26 and 1 a.m. on August 27. The magnets at Eskdalemuir and Richmond (Kew Observatory) were considerably disturbed, especially at the former station. The full amplitude of the disturbance there in the north and vertical components cannot be assigned, owing to the limit of registration being passed, but the range in each element considerably exceeded 400 $\gamma$ ($1\gamma \equiv 1 \times 10^{-5}$ C.G.S.), and in the west component it was fully 300 $\gamma$. At Kew the ranges of the horizontal force and vertical force were approximately 250 $\gamma$ and 200 $\gamma$ respectively. Declination at Kew had a range of 27′, the most rapid movements occurring early on August 27; the extreme easterly position was reached at about 2.5 a.m., and the extreme westerly at about 2.35 a.m.

A notable feature, especially at Eskdalemuir, was the "sudden commencement," introducing the storm at about 7.45 p.m. on August 26. Its oscillatory character was particularly well shown in the north component, a very rapid fall of 11 $\gamma$ preceding a rapid rise of 100 $\gamma$. After this commencement the horizontal component at Eskdalemuir and Richmond (Kew Observatory) remained above its normal value until about 10 p.m., when it fell below normal and remained so, while oscillating considerably, during the rest of the disturbance. The depression in the horizontal component at Kew Observatory at 6 a.m. on August 27, when the storm was nearly over, exceeded 100 $\gamma$. An interesting feature in the vertical force curves at Eskdalemuir towards the end of the storm after 6 a.m. on August 27 is a series of oscillations of short period, averaging about 4·6 minutes, which recall a similar phenomenon observed there in the storm of November 5-6, 1915.

---

THE display of Aurora Borealis on August 26–27 was observed by Dr. John Satterly in Canada. Writing from Jackson's Point, Lake Simcoe, Ontario, Dr. Satterly says that on August 26 the whole northern sky from horizon to zenith was illuminated for several hours. On the horizon there was a strong yellowish glow with streamers radiating upwards. Arcs of light encircled the zenith, and flickering bands and patches of colour were seen in middle altitudes. The smallest newspaper headlines could be read at 11 p.m. On August 28 the northern lights were feeble, but at 10.30 p.m. (Eastern time) an immense riband of light, practically a complete semicircle, spread across the sky. It extended from the east and rose a few degrees sected the Milky Way at about 60° or 70°, very nearly at the zenith; it was much brighter and narrower and more definite than the Milky Way. No portion of the arc appeared in the northern sky. At 11.15 p.m. the western half faded away gradually, and at 11.30 p.m. the eastern half vanished.

---

## THE SAKURA-JIMA ERUPTION OF JANUARY, 1914.

PROF. OMORI has recently published a second valuable memoir on the eruption of Sakura-jima, which occurred on January 12, 1914.[1] The volcano lies in Kagoshima Bay, in South Japan, a few miles to the east of the city of Kagoshima. Until the last eruption Sakura-jima was an island. It is now connected by a lava-stream with the east side of the bay. The part of the bay lying to the north of Sakura-jima ranges in depth from 70 to 107 fathoms, and is apparently of the same origin as the deep lakes which are found behind the sea-coast volcanoes of Usu-san and Tarumai-san.

*Displacements of the Ground.*—Soon after the eruption it was noticed that the sea-level had undergone an elevation relatively to the adjoining coast. At high tides the low districts at the south end of Kagoshima were flooded. Along the north-west and north coasts of Kagoshima Bay the rise of the water was still greater, embankments and stone walls being damaged and extensive rice-fields devastated. The amount of the sea-level elevation was nearly a metre at Kagoshima and two metres or more in Sakura-jima. The apparent sea-level elevation was greatest at the end of 1914, after which it began to decrease.

Prof. Omori attributes this change to the depression of the ground in the neighbourhood of Sakura-jima in consequence of the great eruption. This depression was revealed with greater precision by a renewal of the Military Survey levelling of the district and of the levelling along the railway lines near Kagoshima Bay. Prof. Omori has represented the results on a map on which are drawn the curves of 50, 100, 300, and 500 mm. depression. The curves of 300 and 500 mm. run close to the coast of the northern portion of Kagoshima Bay. The axes of these curves, which are directed north and west respectively, intersect in a point lying off the north coast of Sakura-jima, and Prof. Omori regards this point as indicating the centre of the area of greatest depression of the ground. The total depression-volume within the 100-mm. curve is 1·35 c. km. The aggregate volume of lava flows and pumice and ash ejection during the recent explosion is about 2·2 c. km.

It is important to notice that the point of maximum depression, which probably coincides with the principal centre of the lava reservoir, lies, not under Sakura-jima, but in the region between it and the active volcano of Kirishima.

The triangulation surveys of 1898 and 1914 also reveal considerable displacements, both horizontal and vertical, in Sakura-jima, while the coast of the island is everywhere depressed. Three points in the interior have been raised 0·14 and about 9·7 and 10·4 metres. The horizontal displacements in the north-west of the island vary from 2·04 to 3·62 metres towards the south, and in the west and north by amounts from

Digitized by Google

Moreover, displacements of 0·53 to 0·95 metre along the west coast of Kagoshima Bay converge with those in the west and north of Sakura-jima towards an elliptical area which agrees roughly with the area of greatest depression.

*Propagation of Sound-Waves.*—Prof. Omori divides the sounds which accompanied the eruption into three groups: (1) the early sounds heard from about 10 a.m. to the afternoon of January 12; (2) the strong detonations from 6.30 p.m. on January 12 to 6 a.m. on January 13; and (3) the much weaker sounds of the after-explosions for about ten days following the great eruption. All these sounds were heard within two entirely detached areas, and it is remarkable how similar these areas are in form and to some extent in magnitude. The area which includes the volcano extends in each case in an easterly direction, the mean radius of the boundary being 111, 114, and 102 km. for the above three classes of sounds. The second area lies to the north of the other, and is elongated from west to east, the mean radial distance of its central line from the volcano being 195, 177, and 196 km. The width of the silent zone was 40–50 km. for the strong detonations and about 108 km. for the after-explosions, the axis of the silent zone, in both cases, being at a distance of about 120 km. from Sakura-jima. The greatest distance to which the detonations were heard is about 500 km. (or 310 miles) towards the north-east, but the air-vibrations were strong enough to shake houses and doors for about 85 km. farther in the same direction.

C. DAVISON.

## THE BRITISH ASSOCIATION AT NEWCASTLE.

### SECTION E.

#### GEOGRAPHY.

OPENING ADDRESS (ABRIDGED) BY EDWARD A. REEVES, F.R.A.S., F.R.G.S., PRESIDENT OF THE SECTION.

THE surveying equipment of the pioneer explorer of early days, say, of from twenty to sixty years ago, usually consisted of a sextant and artificial horizon, a chronometer or watch, prismatic compass, boiling-point thermometers, and aneroid. With the sextant and artificial horizon the astronomical observation for latitude and longitude were taken, as well as those for finding the error of the compass. The route was plotted from the compass bearings and adjusted to the astronomically determined positions. The latitudes were usually from meridian altitudes of the sun or stars, and longitudes from the local mean time derived from altitudes east or west of the meridian, compared with the times shown by the chronometer, which was supposed to give Greenwich Mean Time.

The sextant, in the hands of a practical observer, is capable of giving results in latitude to within 10″ or 20″, provided it is in adjustment, but the difficulty is that the observer has no proper means of testing for centring and graduation errors.

The great drawback to the sextant for survey work is that it is impossible to take accurate rounds of horizontal angles with it, since, unless the points are all on the same level, the angles must be too large. It is essentially a navigator's instrument, and nowadays has been almost entirely superseded by the theodolite for land-surveying.

As regards the longitude, the difficulty was always to obtain a steady rate for the chronometer, owing principally to the unavoidable oscillations and concussions met with in transit. Formerly it was customary to observe lunar distances for getting the Greenwich Mean Time instead of trusting to the chronometers, but these, even with the utmost care, are very unsatisfactory.

In more recent years the occultation of a star method of finding the Greenwich Mean Time superseded almost entirely the lunar distance, but all these so-called "absolute" methods of finding longitude are fast becoming out of date since the more general introduction of triangulation and wireless telegraphy.

Heights of land were usually obtained by the boiling-point thermometer or aneroid.

This, then, was the usual equipment of the pioneer. With such an outfit the greater part of the first mapping of Africa and other regions of the world was carried out, with results that were more or less trustworthy according to the skill of the explorer and the time and opportunities at his disposal.

In recent years considerable improvement has been made in the instruments and methods of the geographical surveyor; the introduction of the invar tape for the measuring of the base lines, the more general application of triangulation, the substitution of the theodolite for the sextant, the use of the plane-table for filling in the topographical details of the survey, the application of wireless telegraphy to the determination of longitudes, these and other improvements have all tended to greater accuracy and efficiency in geographical and topographical mapping, so that in many respects the rough approximate methods of the earlier explorers are fast being superseded by instruments and methods more in keeping with modern requirements in map-making.

Still, the principle underlying all surveying is the same, and the whole subject really amounts to the best and most accurate methods of measurement with a view of representing on a plane, on a greatly reduced scale, the leading features of a certain area of the earth's surface in their relatively correct positions; and so it resolves itself into geometrical problems of similar angles and proportional distances. This being the case, it is clear that it becomes in the main a question of correct angular and linear measurements, and all the improvements in survey methods have had for their object the increased accuracy of accomplishing this, together with greater facility for computing the results.

What we do now is exactly what was attempted by the early Greek geometricians and others in ancient times, only we have far more accurate instruments. If, for instance, we compare our modern micrometer theodolite with the old scaph of the Greeks the contrast is striking, although both had the same object in view as regards taking altitudes of heavenly bodies. Many of the old instruments, in spite of their great size, were extremely rough, and the angles could only be read with approximation or to a great extent by estimation, while the theodolite, which is now generally used on geographical surveys, although it has circles of only five inches in diameter, can, by means of the micrometers, be read to 2″ of arc, or even to 1″ by careful estimation. This, when one comes to think of it, is a triumph of refinement, since it really means that we can measure to within about 1/80,000 part of an inch, which is something like the space occupied by 1″ on the arc of a circle of 5-in. diameter. At least this is the theoretical accuracy, but in practice there are, of course, errors in sighting, setting the micrometer wires, and those arising from other sources which have to be taken into consideration.

The continued striving after greater accuracy of measurement applies not only to angular measuring instruments, but to linear distance measurement as well; and the improvements in apparatus for this purpose, could we follow them in detail, would be most interesting. From the rough methods that would suggest themselves naturally to early intelligent men,

Digitized by Google

to the modern base-line apparatus, and accurately computed sides of a geodetic triangulation, is a far cry, and the advance in this matter is certainly remarkable.

So far what I have said has had chiefly to do with some of the earlier attempts at surveying and map-making, and the instruments and methods by which these have been carried out; and I will now try to give you an outline of what has been done in comparatively recent times, and state briefly the present position of various parts of the world as regards the condition of their mapping and the survey basis upon which their maps depend.

Little by little civilised man, by his daring, his love of adventure, and the necessities of events and circumstances, has penetrated into the unexplored parts of the earth and pushed back the clouds and mists that so long shrouded them from his knowledge, until at the present time the regions that are entirely unmapped are very few indeed, and do not amount to more than about one-seventh of the whole land-surface of the globe, including the unexplored areas of the polar regions, which may be either land or water. Not content with a mere vague acquaintance, he has striven for greater accuracy, and has turned to various branches of science and called them to his aid, in order that he may obtain more correct knowledge and a better comprehension of the earth's features. To enable him to fix with definiteness the position of places upon its surface, map out the various land-forms, and obtain their accurate measurements, he has consulted the astronomer and mathematician. Commencing with the rudest instruments and measuring apparatus, these, as greater accuracy was required, have gradually been improved, until the present-day appliances and equipment of a surveyor are wonders of refinement and delicacy.

I have attempted to form an estimate of the condition of the world's surveys for 1860 and 1916; and, taking the total area of the land-surface of the earth together with the unknown parts of the Arctic and Antarctic regions which may be either land or water, to be 60,000,000 square miles, I have obtained the following results:—

| | 1860 Sq. stat. miles | 1860 Proportion to whole | 1916 Sq. stat. miles | 1916 Proportion to whole |
|---|---|---|---|---|
| 1. Mapped from accurate topographical surveys based on triangulation or rigorous traverses | 1,957,755 | 0·0326 or roughly $\frac{1}{30}$ | 8,897,238 | 0·1482 or roughly $\frac{1}{7}$ |
| 2. Mapped from less trustworthy surveys, chiefly non-topographical | 2,017,641 | 0·0336 or roughly $\frac{1}{30}$ | 5,178,008 | 0·0866 or just over $\frac{1}{12}$ |
| 3. Mapped from route traverses and sketches | 25,024,360 | 0·4170 or roughly $\frac{2}{5}$ | 37,550,552 | 0·6258 or little less than $\frac{2}{3}$ |
| 4. Entirely unsurveyed and unmapped | 30,997,054 | 0·5166 or just over $\frac{1}{2}$ | 8,370,794 | 0·1391 or little less than $\frac{1}{7}$ |

These proportions can perhaps be more clearly seen from the following diagram (Fig. 1), on which numbers and tintings have the same significance as on the maps and table.

From the figures here given it is plain that with the same rate of progress as that of the past sixty years or so it would take more than four hundred years more to complete the accurate trigonometrical surveying and topographical mapping of the earth's land-surface, including the parts of the polar regions that may possibly be land—that is, the 60,000,000 square miles which we have taken for this total area; but this will certainly not be the case, since the rate at which such surveys have been carried out has been greatly accelerated during recent years, owing to the rapidly increasing demands for [illegible] development, are properly surveyed and mapped. There are, of course, regions, such as those near the poles and in the arid deserts, that are never likely to be accurately triangulated and mapped to any extent, and it would be mere waste of time and money to attempt anything of the kind.

From its very foundation the Royal Geographical Society has had a remarkable influence on the surveying and mapping of the earth's surface, and especially those parts of it which have been previously but very imperfectly known or entirely unexplored. I think it must be admitted that this influence has increased as years have gone by, and it is no exaggeration to say that it has done more in this respect than any other body. It is therefore perhaps fitting that I should give some account of what has been accomplished, as it has a direct bearing on route-surveying and mapping by travellers and explorers. It is not only by the awarding of annual medals to explorers whose journeys have resulted in an increase to our geographical knowledge, and the more accurate surveying and mapping of little-known parts, that the society has stimulated and encouraged geographical research, but it has also assisted financially numerous expeditions, and the money thus granted has enabled many a man to carry out his explorations to a successful issue,

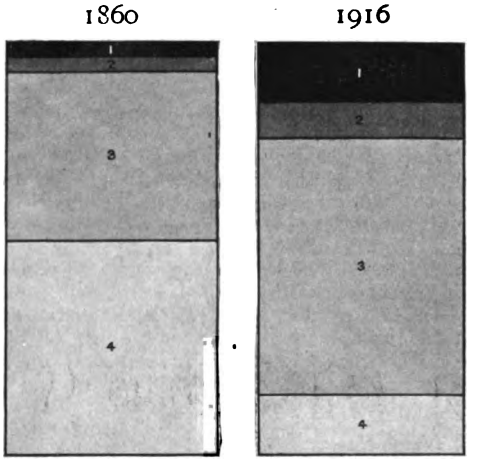

FIG. 1.—Relative condition of world surveys in 1860 and 1916.

which he otherwise could not have done for want of funds. Still more frequently has it been the case that travellers going into little-known parts of the world have been granted loans of surveying instruments which they could not otherwise have taken, and encouraged to do what mapping they found possible. Altogether 331 expeditions have been lent instruments, and about 38,500*l.* have been devoted to grants of money by the society to further geographical exploration and surveying.

There is still another way, by no means the least important, in which the Royal Geographical Society has done much to promote geographical surveying, and that is by providing suitable instruction in the work of surveying for travellers. It is all very well to grant money and lend instruments, but the important thing is to know how to make good use of the money and the instruments so as to take proper advantage of opportunities afforded and to produce the best surveys and maps of the regions visited. In the early days of the society a man had to pick up the requisite [illegible]

Digitized by Google

it forms one of the most important parts of the society's work. This course of instruction in geographical surveying, which has now been in existence for about thirty-eight years, was first conducted by my predecessor, the late Mr. John Coles, and, since he resigned in 1900, has been under my charge. Altogether 725 surveyors and explorers have received instruction, without reckoning special large classes of forty or fifty men which during the past few years, until the outbreak of war, were sent to us by the Colonial Office to learn the more elementary parts of compass-traversing and mapping.

Now as regards the future. The demand for properly trained geographical surveyors has been steadily increasing in past years, and is likely to be still greater as time goes on. After the termination of the war there will be much work to be done, especially as regards the surveying of new boundaries, and freshly acquired districts in Africa and elsewhere; and it would be wise to make preparations for this well ahead.

The future surveyor will be in a much better position than his predecessors, not only on account of the improvements in instruments and apparatus for his work, but because, in many parts, a good beginning has been made with the triangulation to which the new surveys can be adjusted. In Asia a considerable amount of new work of this kind has been done over the frontier of India in recent years by the Survey of India, among the more important of which are the connecting of the Indian triangulation with that of Russia by way of the Pamirs, the surveys of Sir Aurel Stein, Dr. de Philippi, and others. The many boundary surveys that have been carried out in Africa, the triangulations of Egypt, the Sudan, East and South Africa, and other parts of the continent are well advanced, and will be of the utmost value to the future surveyor. One of the most important lines is the great triangulation which, it is hoped, will some day run across the continent from south to north, from the Cape to Egypt. Owing to the energies of the late Sir David Gill, this important chain of triangles has already got so far as the southern end of Lake Tanganyika; the part to the west of Uganda, near Ruwenzori, has also been finished, and it now remains to carry the chain through German East Africa and down the Nile Valley. The latter, it is hoped, will by degrees be accomplished by the Sudan and Egyptian Survey Departments, although it may be delayed for some years yet; and the former, which was to have been undertaken by the Germans, it is to be hoped will, after the war, be accomplished by British surveyors, through—not German East Africa—but newly acquired British territory. Running right through parts of Africa that are but imperfectly mapped in many districts, the stations of this triangulation will be invaluable for the adjustment of any network of triangulation for future surveys in the interior, and, indeed, has already been utilised for the purpose.

The carefully carried out boundary surveys between various countries of South America will be of the greatest assistance in future exploration and survey in the interior of that continent, wherever they are available, while the Survey Departments of Canada and the United States are doing excellent work and extending their surveys far into the imperfectly mapped regions of North America. So, altogether, the surveyor of the future will soon have a good foundation of trustworthy points to work from. It is important to remember that running a chain of triangles across a country, though important as a framework, does not constitute a map of the country; and what is wanted is a series of good topographical maps, based upon triangulation, showing the leading features with sufficient accuracy for the purposes of ordinary mapping, so that on scales of 1 : 250,000, or even 1 : 125,000, there is no appreciable error.

As regards instruments, the astrolabe à prisme is being increasingly used for taking equal altitude observations with most excellent results, but at the present time the 5-in. transit micrometer theodolite, already referred to, is perhaps all that is required for general work. It has now been thoroughly tested and found most satisfactory. As regards smaller instruments, there is the 4-in. tangent-micrometer theodolite, and for rapid exploratory survey, where weight is a great consideration, a little 3-in. theodolite has been found useful.

For base-line measurement the invar tape should be taken on all serious work, and for filling in the topographical features a good plane-table is doubtless the instrument to use. In mountainous regions and in some other special conditions photographic surveying doubtless has a future before it, and in military operations when the photographs are taken from aircraft it has proved itself invaluable; but in ordinary surveying it is, I think, not likely to take the place of well-established methods. The introduction of wireless telegraphy for the determination of longitude is likely to increase in usefulness. Good examples of the work done with it have lately been given in the *Geographical Journal* and elsewhere.

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

LEEDS.—The urgency in the demand for the training of colour chemists and dyers has led to a reorganisation of this department of the university. The newly appointed head of the department is Mr. A. G. Perkin, F.R.S., who is assisted in the theoretical and practical teaching of colour chemistry by Dr. J. B. Oesch, formerly colour chemist in one of the chief Continental factories, whilst that of dyeing is under the special supervision of Mr. G. H. Frank, Mr. P. King, former chemist to Messrs. Courtaulds, Ltd., and Mr. A. E. Woodhead. In addition to systematic instruction in the above branches of technology, opportunities will be afforded to students of hearing special courses of lectures on "Cellulose" by Mr. C. F. Cross, on "The Distillation of Coal Tar" by Mr. H. P. Hird, and on "Colour in its Relation to Constitution" by Prof. E. R. Watson, of Dacca University.

At the request of British Dyes, Ltd., a laboratory has been set apart for the accommodation of a staff of chemists working on behalf of this firm, and will be exclusively in charge of a member of the university staff. The department is controlled by the Textile Industries and Dyeing Committee of the university, consisting of well-known representatives of both industries. The aim of the newly organised department is therefore to render service to the colour-making and dyeing industries by offering special training in these branches, whilst giving assistance to the enterprise promoted by Government money.

MR. E. A. WOODS, of New College, Oxford, has been awarded a Burney Yeo scholarship for 1916 at King's College Hospital Medical School.

MR. W. NEILSON JONES, late assistant-lecturer in botany at Bedford College for Women, N.W., has been appointed lecturer and head of the department in botany of the college.

THE sum of 300*l.* has been left to the Bristol General Hospital by Dr. W. Barrett Roue to found a scholarship for medical students of the hospital. The scholarship will be known as the "Barrett Roue Scholarship."

BY the will of Sir James Sivewright, whose death was announced last week, legacies are bequeathed of 5000*l.* to Milne's Institution, Fochabers, and of 10,000*l.* to the University of Aberdeen, for the purpose of providing bursaries for students coming from the county of Morayshire.

THE resignation of Dr. R. Armstrong-Jones of the medical superintendency of the Claybury County Asylum was announced in our issue of August 10. To mark the esteem in which Dr. Armstrong-Jones is held by the staff of the asylum a silver tea and

THE calendar for the current session of Birkbeck College, London, provides full particulars of the numerous day and evening classes in the subjects included in university faculties of arts, science, laws, and economics. The character of the work accomplished at this institution is well summarised in the final report of the Royal Commission on University Education in London (1913). The commissioners write: "We think that the original purpose of the founder of Birkbeck College and the excellent work that institution has done for the education of evening students who desire a university training mark it out as the natural seat of the constituent college in the faculties of arts and science for evening and other part-time students."

THE prospectus and time-table of the Belfast Municipal Technical Institute for the current session show convincingly the care and thoroughness with which the Technical Instruction Committee of the city has provided instruction in the principles of the arts and sciences which bear directly or indirectly upon the trades and industries of Belfast. The prospectus describing the work of the various departments runs to 384 closely printed pages, and every subject likely to be of service to the men and women engaged in the city's industries seems to be included in the time-table. The day technical college provides instruction in the science and technology of mechanical engineering, electrical engineering, the textile industries, and pure and applied chemistry. The Queen's University of Belfast and the Corporation of Belfast have entered into an agreement whereby the institute is recognised as a college in which students of the University may pursue a course of study qualifying for a degree of the University.

THOUGH the governors of the Royal Technical College, Glasgow, in view of the war, reserve full power to modify the arrangements announced in the recently published calendar for the session 1916–17, they again offer suitable educational facilities for those who wish to qualify themselves to enter upon one of the industrial professions, or to follow one of a number of selected trades. Complete courses of instruction are provided in mathematics, physics, chemistry, the principles of engineering, and other subjects, and in their application to industries and arts. The college is affiliated to the University of Glasgow, and candidates for the degree of B.Sc. in applied science may attend the necessary qualifying courses either in the University or in the college. The University of Edinburgh, too, has recognised the day classes of the college as qualifying for its degree in science. Numerous important firms have expressed their willingness to allow a selected number of their apprentices facilities for carrying out a scheme of college study conjoined with practical work, and some are willing to recognise the time spent in college as part of the apprenticeship period.

NOTHING perhaps could be more opportune to the cause of educational reconstruction than the recent publication by the Board of Education of the pamphlet entitled "The Admiralty Method of Training Dockyard Apprentices." By its system of training the Admiralty has succeeded in providing on one hand a body of leading technical experts in shipbuilding and engineering, and on the other a body of skilled workmen among whom the labour troubles that have so sorely affected employers elsewhere are practically unknown. Moreover, not only have the Ad-

Digitized by Google

Navy of Japan was likewise laid by the products of this remarkable scheme. It is only natural, therefore, to inquire what are the fundamental characteristics of a system that has achieved such a unique success. The details are described in the pamphlet already mentioned; but it may be stated that the underlying principles consist in the adoption of a military form of organisation dependent almost exclusively upon individual merit, and a method of admission to its ranks as broad as democracy itself. Apprentices enter the Royal Dockyards as the result of a competitive examination, and they are compelled to continue their education by attending the Dockyard schools for twelve hours a week (two afternoons and three evenings), of which seven and a half hours are given by the Admiralty. Apprentices pay no fees for attending the schools, are provided with text-books and stationery free of cost, and are paid their usual wages for the afternoons on which they are at school. Perhaps the most astonishing feature of the whole system lies in the fact that this remarkably democratic scheme was quietly inaugurated in the least expected of our national institutions, and in a time when practically every other form of high professional training in the country was a class privilege. In a crisis like the present, therefore, when the whole of the virtues of a nation are powerless without outstanding leadership and genius, the moral is plain.

## SOCIETIES AND ACADEMIES.

### PARIS.

**Academy of Sciences,** September 4.—M. Camille Jordan in the chair.—G. **Bigourdan**: The conference of longitudes of 1634. A historical account of Morin's proposals.—P. **Zeeman**: Direct measurement of the axial velocity of water in Fizeau's experiment. The axial velocity was formerly determined by measuring the whole of the water passing through the tube, giving the mean velocity, and using the coefficient 0·84 to determine the axial velocity. As this coefficient is liable to uncertainty, a new alternative method is described, based on the introduction of very small air bubbles into the flow, and observing their trajectory by means of a rotating mirror. This has led to an unexpected result: the axial velocity varies in a complicated manner along the tube, so that there is no one axial velocity. The extreme variation is more than 10 per cent. Finally, a standardised Pitot tube was used to measure the velocities at a large number of points, with satisfactory results.—J. **Bougault**: The preparation of acylsemicarbazides, starting from the semicarbazones of α-ketonic acids. The oxidation of semicarbazones by iodine and sodium carbonate, by a quite unexpected reaction, gave a semicarbazide according to the equation, $R.C(CO_2H):N.NH.CO.NH_2+O = CO_2+R.CO.NH.NH.CO.NH_2$. The reaction is completed at the ordinary temperature, and its generality is shown by the examples given, in which R is $(C_6H_5.CH_2)$, $(C_6H_5.CH_2.CH_2)$, $(C_6H_5)$, and $((CH_3)_2.C)$. Of the four semicarbazides thus prepared, three are under the treatment.—J. **Danysz**: The causes of the disturbances observed after the injection of products of the arsenobenzene group, and anaphylactic crises. A study of the conditions producing a precipitate in the veins after injection of arsenobenzene derivatives.—L. **Camus**: The preparation, properties, and advantages of a homogeneous vaccine.

| ⅙ ,, | 0.95 | 6 | 0 0 | 1/12 ,, | 1.40 | 10 | 10 0 |

☞ NATURE *says*: "*Compare very favourably in all respects with similar lenses of other makers at double the price.*"

81 TOTTENHAM COURT ROAD, LONDON, W.

*Part III. JUST PUBLISHED.*

To be issued in Six Parts. Med. 8vo. Each at 6s. net.

# A BIBLIOGRAPHY OF BRITISH ORNITHOLOGY

FROM THE EARLIEST TIMES TO THE END OF 1912

INCLUDING

Biographical Accounts of the Principal Writers and Bibliographies of their Published Works

By W. H. MULLENS, M.A., LL.M., F.L.S., M.B.O.U., and H. KIRKE SWANN.

*** The aim of the authors has been to give a biographical account of each author or co-author of a separately published work, followed by a complete bibliography of published works or contributions to works, and of papers contributed to Journals (where such exceed one page in extent), bearing on British Ornithology.

Collations are given in all possible instances, together with verbatim spaced titles of separate works published before 1850, and shorter titles of those published since that date. Critical notes on many of the books are also included.

To this it is intended to add by way of Supplement a Geographical Bibliography, in which the books and articles, as well as the ornithological matter in topographical books, will be arranged under their separate counties, thus affording an index to the work accomplished in the various districts.

A Chronological Index to separate books published before 1850 will also be included.

MACMILLAN & CO., LTD.,

ST. MARTIN'S STREET, LONDON, W.C.

## W. H. HARLING'S NEW ENGINEER'S SET

of Electrum Instruments

In round cornered, leather-covered case, containing full set, comprising: Half set, hair spring divider, ink and pencil bow compasses, 3 spring bows, 2 drawing pens, keys, spare leads and needles. All points are nut-and-bolt needles. Price £23. 3. 0

¶ My Instruments always have been, and still are, manufactured in my own London factory.

W. H. HARLING. Mathematical, Drawing, and Surveying Instrument Manufacturer.

47 FINSBURY PAVEMENT, LONDON, E.C.; AND AT GROSVENOR WORKS, CLAPTON, N.E.

# What Therapeutists think

The following list of advantages of the Coolidge Tube, is compiled from a report of a recent meeting of Electro-Therapeutists. The appreciations expressed confirm our claim that

## The COOLIDGE X-Ray Tube

is the greatest advance yet in X-ray Tubes

"The Coolidge Tube possesses the quality of extreme durability."

"It can be used continuously for long periods without risk of damage to the tube, with currents of any strength likely to be required for examination."

"Four or five milliamperes can be passed through it continuously for many years."

"It is an instrument of precision and in advance of anything of its kind yet produced."

"It is easily adjusted for use in various parts of the body and can be so arranged as to give off rays of varying penetrative power."

"For single flash exposures it constitutes the ideal tube."

"The tube can be altered from "soft" to considerable "hardness" in a few seconds."

"The chief merit of the tube was seen in therapeutic work—indeed it would be difficult to conceive of any improvements likely to render it more efficient."

"Within reasonable safety limits it could be used for many hours daily and at the end of the day would continue its output of quite uniform radiations."

"The tube made it possible to attack a deep seated growth from all aspects."

"The advent of the Tube has opened up many interesting fields of experimental research. One Coolidge Tube had been used for fourteen months for deep therapy, and no one who had employed The Coolidge Tube would revert to the ordinary X-ray Tube."

"It saves an enormous amount of time."

"It could always be adjusted to any required penetration, hence an exact repetition of the dose could be given."

"It was found particularly good for epilation."

"When in working order the tube requires no cooling mechanism."

"For bismuth-meal radioscopy the Coolidge Tube is ideal."

"Radiographers and physicists owe a great debt of gratitude to Mr. Coolidge for his invention, which is regarded as the most wonderful X-ray Tube that has ever been constructed, and much more will be revealed by it in future."

*The Coolidge Tube can be demonstrated by and obtained immediately from the principal dealers in X-ray apparatus.*

THE MANCHESTER MUNICIPAL

## SCHOOL OF TECHNOLOGY

(UNIVERSITY OF MANCHESTER).

PRINCIPAL: J. C. M. GARNETT, M.A. (late Fellow of Trinity College, Cambridge).

The Prospectus, forwarded free on application, gives particulars of the courses leading to the Manchester University degrees in the Faculty of Technology, in the following departments:—

MECHANICAL ENGINEERING,
ELECTRICAL ENGINEERING,
SANITARY ENGINEERING (including Municipal Engineering),
THE CHEMICAL INDUSTRIES (including General Chemical Technology, Bleaching, Dyeing, Printing, Papermaking, Brewing, and Metallurgy),
THE TEXTILE INDUSTRIES,
PRINTING AND PHOTOGRAPHIC TECHNOLOGY,
MINING,
ARCHITECTURE.

During the Session 1916–1917, First Year Courses will be specially adapted to the requirements of students who may wish to take Commissions in H.M. Forces.

## BOROUGH POLYTECHNIC INSTITUTE, BOROUGH ROAD, S.E.

CHEMISTRY DEPARTMENT.

UNDER THE DIRECTION OF C. DORÉE, M.A., D.Sc.

The Classes in Elementary and Advanced Inorganic and Organic Chemistry commence September 25, 1916.

The following Special Evening Courses in Applied Chemistry will be arranged:—

The Chemistry and Technology of the Essential Oils.

The Analysis of Laundry Trade Materials.

Attention is also directed to the facilities available for special work in Electrochemistry, Foodstuff Chemistry and Manufacture, and the Chemical Technology of Cellulose.

For full particulars apply

C. T. MILLIS,
Principal.

## THE UNIVERSITY OF SHEFFIELD.

EDGAR ALLEN SCHOLARSHIPS

The following ENTRANCE SCHOLARSHIPS, each of the value of £100 per annum, and tenable for three years, are offered:—

(*a*) TWO SCHOLARSHIPS, open to men and women who will not have completed their 20th year at the beginning of the University Session in which they enter the University.

(*b*) TWO SCHOLARSHIPS, restricted to the "sons of workmen earning daily or weekly wages and foremen of workmen and managers."

An examination for the above Scholarships will be held in December next, and entries must be sent to the REGISTRAR by October 31.

Full particulars of these Scholarships may be obtained free from

W. M. GIBBONS, Registrar.

## THE UNIVERSITY OF SHEFFIELD.

COURSES are held and DEGREES are awarded in the following Faculties: ARTS (including Architecture), PURE SCIENCE, MEDICINE, LAW, APPLIED SCIENCE (including Engineering, Metallurgy, Mining, and Glass Technology).

The SESSION 1916–17 commences OCTOBER 4, 1916.

Entrance and Post-Graduate Scholarships are awarded each year.

Prospectuses, giving full information, may be obtained from

W. M. GIBBONS, Registrar.

## NORTHAMPTON POLYTECHNIC INSTITUTE, LONDON, E.C.

TECHNICAL OPTICS DEPARTMENT.

Applications are invited for the full-time post of LECTURER and DEMONSTRATOR in the OPTICAL LABORATORIES. The salary will depend upon qualifications and experience. For particulars and application forms apply to

R. MULLINEUX WALMSLEY, D.Sc.,
Principal.

## JOURNAL OF THE ROYAL STATISTICAL SOCIETY.

# Whatman Filter Papers are British

**TESTS have proved their high quality for careful and accurate work. Use Nos. 1-5 for general filter purposes; the remainder are Acid Extracted Grades.**

**No. 1.**
For general quantitative and qualitative work. Retains Barium Sulphate. Equivalent to C. S. & S. 595.

**No. 2.**
Similar to the No. 1, made slightly heavier. Rapidly filters fine precipitates. Leaves clear, bright filtrate. Equivalent to C. S. & S. 597.

**No. 3.**
A still heavier paper adapted to pressure and vacuum filtration. Filters fairly fast, yet retains fine precipitates. Equivalent to C. S. & S. 598.

**No. 4.**
Very soft, open in texture. Rapidly and perfectly filters fruit juices, syrups, oils, varnishes, etc. Equivalent to C. S. & S. 604.

**No. 5.**
A specially hardened paper of great purity. Very strong; retains finest precipitates. Equivalent to C. S. & S. 602.

**No. 30.**
Hydrochloric acid treated. Low ash, close texture. For quantitative work. Equivalent to DREVERHOFF 207.

**No. 40.**
A paper treated by both Hydrochloric and Hydrofluoric acids. Has less ash than No. 30. For very accurate quantitative work. Retains finest precipitates. Equivalent to C. S. & S. 589 (White Ribbon).

**No. 41.**
Treated same as No. 40, but more open and filters more quickly. Not recommended for filtering very fine precipitates unless properly precipitated. Equivalent to C. S. & S. 589 (Black Ribbon).

**No. 42.**
A new grade, resembling Nos. 40 and 41 in chemical qualities, but differing in its physical properties, being much harder and extremely close in texture. Suitable for use in filter pumps. Equivalent to C. S. & S. 589 (Blue Ribbon).

**Nos. 43 & 50, also Folded Filters & Fat Extraction Thimbles, will be out shortly**

**ENGINEERING DAY COLLEGE.**

Full Day Courses in the Theory and Practice of Civil, Mechanical, and Electrical Engineering will commence on Monday, October 2, 1916. The Courses in Civil and Mechanical Engineering include specialisation in Automobile and Aeronautical Engineering, and those in Electrical Engineering include specialisation in Radio-Telegraphy.

*Entrance Examination* on Tuesday and Wednesday, September 26 and 27, 1916. These courses include periods spent in commercial workshops, and extend over four years. They also prepare for the Degree of B.Sc. in Engineering at the University of London. Fees £15 or £11 per annum.

*Three Entrance Scholarships* of the value of £52 each will be offered for competition at the Entrance Examination in September, 1916.

**TECHNICAL OPTICS.**

Full and Part Time Courses in all branches of this important department of Applied Science will be given in specially equipped laboratories and lecture rooms. *An Aitchison Scholarship* (value £30) will be offered in this department at the Entrance Examination.

Full particulars as to fees, dates, &c., and all information respecting the work of the Institute, can be obtained at the Institute or on application to

R. MULLINEUX WALMSLEY, D.Sc., Principal.

## BOROUGH POLYTECHNIC INSTITUTE, BOROUGH ROAD, S.E.

CHEMISTRY DEPARTMENT.

UNDER THE DIRECTION OF C. DORÉE, M.A., D.Sc.

The Classes in Elementary and Advanced Inorganic and Organic Chemistry commence September 25, 1916.

The following Special Evening Courses in Applied Chemistry will be arranged:—

The Chemistry and Technology of the Essential Oils.

The Analysis of Laundry Trade Materials.

Attention is also directed to the facilities available for special work in Electrochemistry, Foodstuff Chemistry and Manufacture, and the Chemical Technology of Cellulose.

For full particulars apply

C. T. MILLIS,
Principal.

**BACTERIOLOGY AND PATHOLOGY.**

## KING'S COLLEGE, LONDON.

UNIVERSITY LABORATORIES,
62 CHANDOS STREET, CHARING CROSS, W.C.

Bacteriology and Pathology—Professor HEWLETT, Dr. F. E. TAYLOR, and Dr. HARK.
Microscopy—Mr. J. E. BARNARD, F.R.M.S.
Parasitology—Dr. GEORGE C. LOW.

The Laboratory is open daily for Instruction and Research.

For particulars apply to the SECRETARY or to Professor HEWLETT, at 62 Chandos Street.

## THE LONDON SCHOOL OF TROPICAL MEDICINE

(UNDER THE AUSPICES OF HIS MAJESTY'S GOVERNMENT),

CONNAUGHT ROAD, ALBERT DOCK, E.

In connection with the Hospitals of the Seamen's Hospital Society.

SESSIONS COMMENCE OCTOBER 1, JANUARY 15, and MAY 1.

For prospectus, syllabus, and other particulars apply to the Dean, Sir HAVELOCK CHARLES, G.C.V.O., India Office, S.W.

## EDINBURGH & EAST OF SCOTLAND COLLEGE OF AGRICULTURE.

SESSION 1916–17.

The WINTER SESSION begins on TUESDAY, OCTOBER 10.

The DAY CLASSES, in conjunction with certain University Classes, provide full courses of instruction in Agriculture, Horticulture, and Forestry.

Digitized by Google

## BEDFORD COLLEGE FOR WOMEN
(UNIVERSITY OF LONDON),
## REGENT'S PARK, N.W.

SCIENTIFIC INSTRUCTION IN HYGIENE.

MICHAELMAS TERM BEGINS THURSDAY, OCTOBER 5, 1916.

For College Calendar and particulars of Scholarships and Bursaries apply to the PRINCIPAL, Miss M. J. TUKE, M.A.

## THE UNIVERSITY OF SHEFFIELD.

COURSES are held and DEGREES are awarded in the following Faculties: ARTS (including Architecture), PURE SCIENCE, MEDICINE, LAW, APPLIED SCIENCE (including Engineering, Metallurgy, Mining, and Glass Technology).

The SESSION 1916–17 commences OCTOBER 4, 1916.
Entrance and Post-Graduate Scholarships are awarded each year.
Prospectuses, giving full information, may be obtained from

W. M. GIBBONS, Registrar.

## THE UNIVERSITY OF SHEFFIELD.

EDGAR ALLEN SCHOLARSHIPS

The following ENTRANCE SCHOLARSHIPS, each of the value of £100 per annum, and tenable for three years, are offered:—

(*a*) TWO SCHOLARSHIPS, open to men and women who will not have completed their 20th year at the beginning of the University Session in which they enter the University.

(*b*) TWO SCHOLARSHIPS, restricted to the "sons of workmen earning daily or weekly wages and foremen of workmen and managers."

An examination for the above Scholarships will be held in December next, and entries must be sent to the REGISTRAR by October 31.
Full particulars of these Scholarships may be obtained free from

W. M. GIBBONS, Registrar.

## ABERDEEN:
## ROBERT GORDON'S TECHNICAL COLLEGE.

SCHOOL OF DOMESTIC SCIENCE.

The Governors of the College are about to appoint a SCIENCE MISTRESS of the above School, qualified for Chemistry, Physiology, Hygiene. Candidates must be University Graduates. Minimum commencing salary at the rate of £90 per annum. Forms of application, with full particulars, may be had from the SECRETARY AND REGISTRAR, Robert Gordon's Technical College, Aberdeen.

## BOOKS!
**Books on Scientific, Technical, Educational, Medical, all other subjects, and for all Exams.**

**SECOND-HAND AT HALF PRICES: New Books at Discount Prices.**

CATALOGUES FREE. State Wants. Books sent on approval.

**BOOKS BOUGHT: Best Prices Given.**

**W. & G. FOYLE, 121-123 Charing Cross Road, London.**

## SECOND-HAND MICROSCOPES.

OCT 24 1916

THURSDAY, SEPTEMBER 28, 1916.

## INDUSTRIAL ASSOCIATIONS.

WITHIN the last few days we have been given further evidence by manufacturers and commercial men of their intention to organise themselves for the protection and development of British trade and industry, and to provide substantial funds for the promotion of these objects. A circular has been issued by the Executive Council of the Federation of British Industries, which includes many leading representatives of manufacturing and producing industries, inviting firms to join the federation, and to pay an annual subscription of 100*l.* until at least the year 1919. The main objects of the federation are the organisation and development of industry now and after the war, in co-operation with labour and in conjunction with the Government and Government departments. In furtherance of like interests, the Committee of Financial Facilities for Trade has just recommended to the President of the Board of Trade that a British Trade Bank should be established with a capital of 10,000,000*l.*, with the objects, among others, of establishing an information bureau, co-operating with merchants and manufacturers, and affording financial support to promising enterprises. It is suggested that any financial assistance given by the Government to undertakings in connection with what are known as "key" industries should be granted through the medium of the commercial information bureau.

A couple of months ago we described the formation of the Association of British Chemical Manufacturers, with a subscription based *pro rata* on the size of the subscribing undertakings; and the steps taken to organise the British engineering industry into an association were outlined in our issue of August 24. At a meeting held at the Mansion House on September 20 to promote the organisation of British electrical and allied manufactures it was pointed out that the approximate aggregate capitalisation of our engineering works is no 400,000,000*l.*, so that an annual subscription of one-tenth of 1 per cent. of the capital would provide an income of 400,000*l.*

These and other signs show that our leading business men are prepared to do their part towards strengthening British industry and commerce for the competitive struggles of the future is already largely recognised, but we still await the production of a scheme which will show exactly what should be done to promote their practical co-operation. We have had a number of committees and advisory councils appointed, but most of them have devoted themselves chiefly to the collection and collation of opinions, and have originated little in the way of constructive plans of procedure. It is perhaps not so necessary now as it was to convince men of business that scientific research is the basis of progressive industry; what is now required of scientific men and their committees is the preparation of practical plans of campaign which can be placed before associations of manufacturers. We believe that when these schemes are available there will be little difficulty in securing the funds to put them into practice.

One such plan, national in scope and bold in conception, was sketched by Dr. Kenneth Mees in an address printed in NATURE of July 13 and 20. It asked for the establishment of a national industrial research laboratory with a staff of two thousand men, half of whom would be scientifically trained, while the other half would be assistants and workmen. The annual upkeep was estimated to cost about 800,000*l.*, but after a few years the laboratory would probably be self-supporting, and might, indeed, make an annual profit on the original investment. Several years ago Sir Oliver Lodge showed how the University of Birmingham alone could make profitable use of five millions, one million of which would be for a real attempt at scientific research in all departments. He pointed out that hitherto the ideas of this country in education and scientific research have been conceived on a wholly inadequate scale, and without proper appreciation of the vast extent of territory awaiting exploration. The most useful thing that could be done at the present time would be to concentrate attention upon the construction and details of schemes of this kind instead of lamenting the assumed indifference of manufacturers to the help which science can give them. The various committees now in existence would then be in the position of boards of directors having before them for consideration definite plans for the development of their businesses, instead of mere letters of complaint at want of enterprise.

There must, of course, be a joining up of those who are attacking the industrial reorganisation of

Digitized by Google

Trade Bank already mentioned, acknowledged in his speech at the meeting on the neglect of science held last May at the Linnean Society that, as a banker, he had found it a serious drawback to be ignorant of even the most elementary knowledge of the natural sciences. "Perhaps," he added, "if my education had not been neglected on those lines, I should in some cases have been able to avoid supporting some processes of manufacture which were in themselves wrong, or futile, while in other cases I might have been tempted to depart from the very rigid banker's attitude of refusing to give support to any new idea." It is to be hoped that the day is near when no educational course will be considered to be complete unless it includes instruction in the broad facts and principles of natural science, so that men in all walks of life may be able to appreciate possible directions of advance. Scientific thoroughness in detail, and sound factory management, are no doubt two of the conditions of industrial success, but banking facilities are another, and whether they are rightly or wrongly offered often depends, as Mr. Huth Jackson said, upon the possession of sufficient scientific knowledge either to discriminate between undertakings, or to know when to call for expert advice.

It is neither desirable nor necessary that every pupil in school or student at college should be compelled to take up science courses of a specialised kind, but it is essential that they should understand something of the place of science in modern life. Business cannot be learnt in a university or in a technical college, but breadth of view can be gained there, and all can learn that the attitude of mind induced by scientific education is just what is required for the successful development of industry. The changes which have taken place in the condition and needs of business life in recent years render it absolutely necessary to employ men of scientifically trained minds, not only among the captains of industry, but also among what may be termed the non-commissioned officers, and even in the rank and file. Our manufacturers are combining in their own interests, and are prepared to co-operate with education and science in national reconstruction. The time has come for the production of schemes of scientific instruction and research, practical enough to appeal to manufacturers and commercial men, and intended to promote the advance of the organised community.

## SCIENCE AND THE SAVANT.

*Les Allemands et la Science.* By Prof. Gabriel Petit d'*Alfort* et Maurice Leudet du *Figaro*. Préface de M. Paul Deschanel. Pp. xx + 374. (Paris: Librairie Félix Alcan, 1916.) Price 3.50 francs.

THE articles collected in this volume were written by twenty-eight prominent representatives of science and art in France to amplify and enforce for the general public the protest made by the Academy of Sciences in November, 1914, against the German manifesto of October 30 of that year, wherein ninety-three "German intellectuals" claimed for their *Kultur* the hegemony of the world of science.

The book reminds one of an "air with variations." The theme is an oft-quoted remark of Pasteur's: "La science n'a point de patrie; mais l'homme de science en a une." The aria is the admirable preface by M. Paul Deschanel, President of the Chamber of Deputies. In the twenty-eight variations, along with a good deal of repetition about scientific ideas as distinguished from scientific material, there are very marked differences of treatment according as the writer envisages *la science* or *l'homme de science*. The tone ranges from extreme bitterness in an article on "La Thérapeutique Commerciale des Allemands," by Gaucher, and mordant irony in Delage's "Histoire Naturelle du Doctus Bochensis," to an amiable letter by Grasset, who insists that science has no country and will not follow the German savants in their excursion outside the region of science into that in which political or national animus is possible. In the circumstances it is difficult to regard so cosmopolitan an attitude as quite fitting the case. There is more ring of sympathetic resonance in Prof. A. Dastre's views about German mysticism and materialism in relation to science and its progress.

Emile Picard raises the practical question of international co-operation in science after the war, and thereby reminds us that science is not independent of the savant. Science has no country, but the progress of science can only find expression through organisations which have national characteristics. In the long run, truth is the only consideration; but the truths of science are not recognisable at all while they are still in embryo in the researcher's brain, and are not always recognised when they have reached the stage of manuscript or print. The spectacles of prejudice may bring some aspects of truth into brilliant focus, but may distort others beyond recognition; and prejudice may be characteristic of nations as of men. It never helps the progress of science; but unfortunately it may affect the development of the truths of science in other

Digitized by Google

Even genius must begin its scientific career with education; and facilities for education, which include the beginnings of research, afford an opportunity for discouraging genius that is not in line with national prejudice. Science cannot disregard the prejudices of men of science, and these essays show to what disastrous conditions the neglect of that fact has led.

While we in this country were priding ourselves upon our institutions for higher education untrammelled by any consideration except money, and the petty rivalries of corporate bodies, without any formal co-ordination or collective responsibility for meeting the country's requirements, the German State provided ample facilities for education which necessarily attracted students from all countries not so well provided—our own, France, the United States, Japan, and everywhere else. Like the French, we regarded these facilities as an admirable example of magnanimous self-interest and public spirit. We have made a mistake; and our national educational authority, when we get one, would do well to take note of the contribution to the history of science which these nine-and-twenty brief essays provide.

## STAR-BEARINGS FOR NIGHT-MARCHING.

(1) *Steering by the Stars for Night-flying, Night-marching, and Night Boat-work between Latitude 40° N. and 60° N.* With Sketch-maps and Directions for finding the Selected Stars. By Dr. J. D. White. Pp. 32. (London: J. D. Potter, n.d.) Price 1*s*.

(2) *The Stars as Guides for Night-marching in North Latitude 50°.* By E. Walter Maunder. Pp. 72. (London: Charles H. Kelly, 1916.) Price 2*s*. net.

MOST persons who spend any considerable time out in the open during the night not only may at times admire the splendour of the vault of heaven on a clear night, but also learn to recognise the principal features of stellar distribution, and even gain familiarity with the effects of the diurnal and annual apparent motions. Such first-hand knowledge may perhaps be somewhat vague, but a little tuition can render it precise and useful. The necessities of the present time have emphasised one practical application. The heavens encircle the sky-line as with a vast compass-card that with a little skill he who runs may read. We have before us two little books, both written with the identical intention of facilitating the employment of this compass. The only difficulty arises in middle latitudes from the rotation of what is termed in old books the oblique sphere. This difficulty is surmounted in both in the same way, namely, that recently advocated by Lieut.-Col. Tilney, which requires that the progressive true bearings of a few selected conspicuous stars shall be provided. The two books present the data very differently.

(1) In "Steering by the Stars" the true bearings are tabulated for twenty guide stars for five different latitudes, and for each hour of sidereal time linked to G.M.T. by an auxiliary table. The bearings are given in whole degrees clockwise from N = 0° to 360°. By some curious accident the bearing of Spica at setting is twice given incorrectly (pp. 17 and 23). The sketch-maps showing the selected stars are too small to be useful, but probably those whom this very practical book may assist already know the stars.

(2) In "The Stars as Guides" the data, prepared solely for latitude 50° N. and referred to local time, are introduced in descriptive text, gathered in tables, and, again, shown in map form, always subdivided in a way to help assimilation. Separate tables for the eight chief compass bearings give the day of the month for each hour of the night at which the guide stars come on the bearing. The twenty-four maps are the chief feature of the book. The stars are boldly shown in white on a black ground, plotted on bearings (both compass-card and angular). The year is divided into six bi-monthly periods on six series of maps. Each series contains four maps showing the stars in the N., E., S., and W. The apparent paths of sixteen guide stars are represented, with hourly positions marked. The use of the maps is straightforward and is explained on one page of the book. We have noticed only a single slip. Aldebaran is not at the *point* of the Hyades.

The theory is simple; accidents of topography are complications even on the best starlit nights. There is no doubt that a continent might be crossed with the aid of the stars, but a night-march from, let us say, Balham to Fulham might be fraught with unpleasant surprises if sole reliance were placed on stellar guidance.

H. E. GOODSON.

## GENERAL CHEMISTRY.

(1) *A Senior Experimental Chemistry.* By Dr. A. E. Dunstan and Dr. F. B. Thole. Pp. xiii + 522. (London: Methuen and Co., Ltd., 1916.) Price 5*s*.

(2) *A Class-book of Chemistry.* By G. C. Donington. Part iv., *Metals*. Pp. vii + 401 to 534. (London: Macmillan and Co., Ltd., 1916.) Price 2*s*.

(3) *Physical Chemistry for Schools.* By Dr. Henry Hortsman Fenton. Pp. viii + 215. (Cambridge: At the University Press, 1916.) Price 3*s*. 6*d*. net.

(1) YET another text-book of inorganic chemistry! This one is intended for "boys in the upper forms of secondary schools and students in technical institutes." It will be found useful by many others also. It is difficult nowadays to present a systematic course of inorganic and general chemistry with any novelty, nor is the ground covered by the present book very different from that covered by others. What is characteristic is the experimental nature of the treat-

Digitized by Google

ment. Although the course is systematic the endeavour has been made, and made with considerable success, to bridge the gap which too often, unfortunately, separates the lecture from the laboratory. The book is written on the sound principle of uniting the lecture and the laboratory, and for that reason it will probably earn a place for itself among chemical manuals.

(2) This is the fourth and concluding part of the late Mr. Donington's well-known "Class-book of Chemistry." It contains a more extensive and detailed treatment of metals than that already given in an earlier part. The descriptions are lucid, and numerous illustrative experiments have been inserted. The concept of ions in solution, and of reversible reactions, are early introduced, and good accounts are given of electro-chemical processes of extraction and refining. The earlier parts have rendered useful service to the teaching of elementary chemistry, and the present volume is up to the level of those previously issued.

(3) Dr. Fenton's book is significant in being the first serious attempt to deal with a problem of importance—namely, that of introducing a certain amount of instruction in physical chemistry into the school curriculum. Hitherto physical chemistry has suffered not a little from the general impression that it is only for those who possess a more or less advanced knowledge of mathematics. The present work ought to do much to remove this erroneous impression. Of course, one has to bear in mind the immaturity of the pupil, and there are aspects of the subject which should not be attempted. There is no reason, however, why the elements of the kinetic theory and its simpler applications should not be taught. Thermodynamical relations, in the reviewer's opinion, are much too abstract to be dealt with adequately at this stage. This is exemplified in one or two places in the present work, where an attempt is made to deal with them. Thus on p. 25 the logarithmic expression for work done in the expansion of a gas is given, but it is not pointed out that this is the *maximum* work, and that as a matter of fact the work might be anything from zero up to this limit. This would necessitate an account of what is meant by maximum work, and this in turn a statement of what is meant by thermodynamic reversibility. No mention of these points is made, although on p. 169 the term "maximum work" is used in connection with the calculation of the p.d. of an electrode. The greater part of the book is of course devoted to kinetic molecular conceptions, and the treatment is highly successful. The concluding chapter on technical applications is of special importance, as it will serve to do away to a certain extent with another very erroneous idea about physical chemistry, that it has nothing to do with practical problems. As a matter of fact it has everything to do with such problems, and the attempt to inculcate this upon the youthful mind is as praiseworthy as it is necessary.

W. C. McC. L.

## *INDUSTRY AND COMMERCE.*

(1) *Factories and Great Industries, with some Account of Trade Unions, Old-Age Pensions, State Insurance, the Relief of Distress, Hospitals.* By F. A. Farrar. Pp. 90.

(2) *Trade and Commerce, with some Account of our Coinage, Weights and Measures, Banks and Exchanges.* By A. J. Dicks. Pp. 94.

(3) *Ships, Shipping, and Fishing, with some Account of our Seaports and their Industries.* By G. F. Bosworth. Pp. 86. (Cambridge: At the University Press, 1916.) Price 1*s.* 6*d.* each.

THESE three books are the first of a series which is designed to give children information on the industrial and commercial condition of their own country. They deal, generally on historical lines, with the nature of the principal industries, with the machinery of commerce, and with the development of shipping; while forthcoming volumes are announced on agriculture and mining.

The first volume under notice contains brief accounts of the Industrial Revolution; the textile industries; leather, paper, and printing; some great manufacturing towns; trade unionism; factory legislation; and provision for unemployment, sickness, and poverty. The second describes weights, measures, and the coinage; the Post Office; food supply; imports and exports; banking and exchange; trade marks, patents, limited liability, underwriting, the customs and excise. The third volume traces the growth of the ship from early times; the mercantile marine and the great ocean highways; the Royal Navy and its dockyards; the fishing industry; Lloyd's and its work; Trinity House and the lighting of the coast; the Port of London and other great ports. The writing is simple without being very inspiring; the books are well printed on good paper; and each volume contains some twenty illustrations, comprising half-tones, line drawings, and maps.

The series is suitable for boys of fourteen years of age or thereabouts, and the books may be used as supplementary readers in the upper classes of elementary schools and in the lower classes of evening schools. It is to be welcomed as supplying just that information which is necessary to create a sane outlook upon the problems of industry and commerce which, as citizens, boys will be called upon to exercise judgment. It is no use treating citizenship as a collection of ethical principles tacked on to a description of representative government and the administration of justice. The deeper problems of politics are even now, and to a still greater extent in the future will be, technical problems, requiring for their comprehension an adequate knowledge of the way in which this industrial system of ours has come into being, and a general sense of the direction in which it is tending.

Our only fear is that the price of the books will lead to their being used singly, and the pupils

Digitized by Google

will obtain only a partial view. The whole series will be equivalent to a single volume of about 120,000 words, but will compare unfavourably with such a volume in unity and coherence. It is unfortunate that there is so much freedom of choice and so narrow a range of price in books for elementary schools; for unless we can have a more definite practical aim in this and other types of education we must expect variety of training and outlook to give us a babel of tongues instead of a clear, resonant voice upon matters of national welfare.

## OUR BOOKSHELF.

*The Thermodynamic Properties of Ammonia.* Computed for the use of Engineers from new experimental data derived from investigations made at the Massachusetts Institute of Technology. By F. G. Keyes and R. B. Brownlee. Pp. v+73. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1916.) Price 4s. 6d. net.

THIS book contains the results of an experimental investigation carried out during the course of several years in the Research Laboratory of Physical Chemistry of the Massachusetts Institute of Technology. The object of the research has been to determine the vapour-pressure curve and the specific heat-capacity of liquid ammonia and the isotherms of the substance, so that the already existing data might be critically examined and supplemented and the results obtained used as a basis for the computation of a new table of the thermodynamic properties of ammonia which would prove useful in controlling the performance of refrigerating machines.

The first part of the book deals with the fundamental thermodynamic relations and a discussion of the data and the computations. The various formulæ involving the relations between the entropy, Gibbs's heat-function, the latent heat, the specific heats along the saturation line, the ordinary specific heats, etc., are obtained and tabulated for convenience. There are discussions on the methods employed to calculate the heat of vaporisation, the specific heat of liquid ammonia, and the entropy and specific heat of ammonia vapour.

The second part of the book gives some forty pages of tables, in which the thermodynamic properties of the saturated and superheated vapour are given with the temperature as independent variable in one set and the pressure in another. A Mollier diagram, in which heat-content is plotted against entropy, is added at the end of the volume.

The book should prove of the greatest service in engineering practice, especially for those who have to deal with refrigerating machines. The tables are given in a very convenient form, and the explanatory matter at the beginning is adequate and lucid. J. R.

*The Journal of the Institute of Metals.* Vol. xv. Edited by G. Shaw Scott. Pp. viii+392. (London: Published by the Institute of Metals, 1916.) Price 21s. net.

THIS volume contains the papers presented at the annual meeting of the institute, with the discussion and correspondence to which they gave rise, together with abstracts of papers relating to the non-ferrous metals and the industries connected therewith. Among the papers is the Third Report to the Corrosion Committee, of which an account was given in NATURE on April 6. The paper by Mr. Withey on the analysis of aluminium and its alloys is a very good piece of work which will probably constitute the standard of reference for some years. The aluminium of to-day is liable to contain copper, iron, zinc, silicon, silica, nitrogen, and sodium. It contains notably more copper than the metal produced ten years ago, but in other respects is a purer metal.

Prof. Stansfield's paper on electric furnaces as applied to non-ferrous metallurgy contains much interesting and valuable information. Furnaces are classified under two main headings: (*a*) those in which metals are reduced from their ores; (*b*) those in which metals are heated, melted, refined, and distilled. The former are electrolytic furnaces, and are used for the production of metals by the electrolysis of their fused salts. Aluminium, sodium, potassium, magnesium, calcium, barium and strontium are produced largely, if not exclusively, in this manner; and other metals, such as zinc, are occasionally so obtained. The latter are electrothermic smelting furnaces, and are used for the production of metals from their ores with the aid of electrically generated heat. Occasionally the metal is present in the ore in the native state, but usually it is found as an oxide or other chemical compound, from which it must be liberated by a chemical reaction involving the use of carbon or some other reagent in addition to the necessary electrical heat.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### Science in Education.

WE hear much of the place of science in education, but it seems sometimes as if its advocates would say: "When I mention science I mean experimental science, and not only experimental science, but industrial science, and not only industrial science, but paying science"—to paraphrase Thwackum.

Let us look at the French conception of science, as summarised in two fat volumes describing its progress in France, for the San Francisco Exhibition. In one volume are philosophy, sociology, education, mathematics, astronomy, physics, chemistry, mineralogy, geology, palæontology, biology, medicine, and geography. In an equal volume are Egyptology, classical

Digitized by Google

archæology, history, art, linguistics, Indics, Sinics, Hellenics, philology (Latin and Celtic), French language and literature, Italian, Spanish, English, German, law, and economics.

Now, this is what science means to France. How shall we give it honour here? The study of man holds as large a place as the study of Nature. And in this study of man language is the servant, and not the exclusive master, as it has been made in England.

One of the first steps required seems to be to put the study of man in its place as part of the essential education for all, quite independent of the minority who specialise in dead languages. We need to teach in every school the course of civilisation, its successes and its failures, the grandeur of the characters and thoughts which have stimulated action, to show man as the most potent and ruling influence upon Nature. At present, to even the small minority who master dead languages for effective use, most of the literature is unknown, and the physical facts of civilisation are ignored. The time spent in general education upon dead languages—mostly ineffective—would suffice for a fair acquaintance with both man and Nature, if practically used. F.R.S.; F.B.A.

### The Third Fossil Tsetse-Fly.

AMONG some fossil insects collected in the Miocene shales of Florissant, Colorado, by Mr. Geo. Wilson, and transmitted to me by Mr. F. H. Ward, I find a beautifully preserved tsetse-fly. The insect is intermediate in size between the two fossil species previously found (both of which may be seen in the British Museum), and is evidently distinct. It may be called *Glossina veterna*, n.sp., and will be best distinguished by the following measurements in millimetres: length 12·5, length of wing 10·9, length of proboscis 4·1, length and width of abdomen each 5·6. The body and legs are brown or black, the abdomen without dark bands; the wings are hyaline, faintly brownish. The scutellum has long marginal and apical bristles, exactly as in the living species. The post-alar and first dorso-central bristles are also well preserved and normal. The anterior basal cell of the wing is about 0·6 mm. broad at end, its truncate apical end is short, and the lower margin does not bulge much near the end. The abdomen is hairy, as in living species. This excellent specimen affords additional evidence for the existence of two tsetse-flies in the American Miocene, astonishing as the fact is. The new species is nearest to *G. osborni*, but is too large to be the female of that form.

T. D. A. COCKERELL.

University of Colorado, Boulder, August 31.

### The Designation of Hours.

A PROPOS the alteration of official time, now imminent: would it not be a good plan to suggest a modification of time nomenclature? As follows: Midday is 12 noon; well and good. Half an hour later is 12.30 p.m., and we have the confusing spectacle of 11.30 p.m. arriving eleven hours *afterwards*! I suggest, as long as the 24-hour system is followed, that each 12-hour cycle be definitely marked off. Thus half-past 12 (day-time) would be 0.30 p.m., to be followed, quite

## *ARCHÆOLOGY OF THE MIDDLE AMERICAS.*[1]

THE work before us is the third volume of a series devoted to the archæology of the Latin Americas, in which the author contrives to give a general account of this enormous field, mainly based upon a widely scattered and not always easily accessible literature, from the earliest Spanish chronists to the present plethora of Americanists. There are few readable works which take a wider and more scientific view of the main questions, whilst the flood of the more professional publications deals with smaller areas and often intensely with abstruse detail of one or other of the numerous problems.

FIG. 1.—Greater Antilles: Wooden idol. (Scale, one-sixth.) From "Central American and West Indian Archæology."

In this quarter of the globe, from Mexico and the Antilles, and extending far down in western South America, a peculiar and unique kind of civilisation developed, and culminated in two widely separated centres, not in the steamy-hot tropical lands, but literally above them, in the uplands, where a more invigorating climate still repaid agricultural toil. Having dealt first with the Mexican-Maya civilisation, which has spread its influence in ever-weakening waves down to Panama, the author devoted his second volume to South America, the civilisation of which centred in the Peruvian highlands.

Having first treated these north and south centres, with their radiating influence into the Middle Americas, he has shorn these by anticipation. From a broad point of view the present volume could therefore deal only with what was left over, and this residue is of minor importance.

Digitized by Google

The first and larger portion of the book deals with the archæology, ethnology, linguistic divisions, habits, and beliefs of the ancient inhabitants of the present States of Nicaragua, Costa Rica, and Panama. The people belong to the same stock, with modifications, which stretched from the Sonoran region through the whole of Central America far into the western—let us say Andine—portion of the southern continent, leaving the bulk of the latter to what may be called the typical neo-tropical races, notably Guarani, Tupi, Arawak, and Caribs. In conformity with the configuration of the isthmus, the influence from the Inca centre was insignificant in comparison with that from the Maya-Mexican. It is the reverse with the fauna and flora, which naturally date from much earlier epochs with broader contact.

The last hundred pages are devoted to the West Indies. These fairest and most fertile islands being subject to earthquakes, volcanic eruptions, and hurricanes, it is, according to our author, not surprising that their inhabitants developed a religious system which consisted in the main of a propitiation of the powers of Nature. Nevertheless, according to the testimony of C. and F. Columbus, father and son, they seem to have been a kindly, honest, and generous folk, to whom contact with the Spaniards meant speedy extermination.

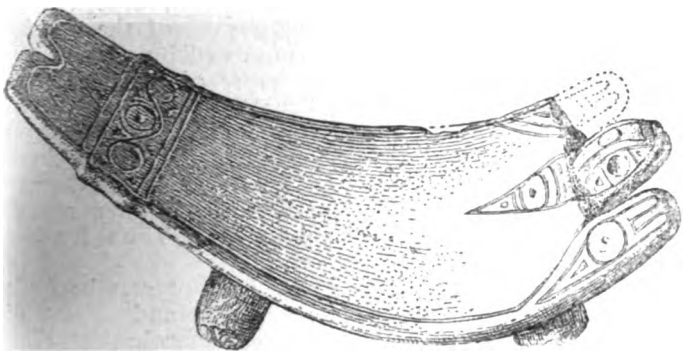

FIG. 2.—Porto Rico: Stone seat. (Scale, one-third.) From "Central American and West Indian Archæology."

The original stock of the whole archipelago were Arawaks from the southern continent, and were in turn followed by the more bellicose Caribs, who at the time of their discovery were in possession of the Lesser Antilles and fast extending into some of the greater islands. They had a patriarchal system, with caciques or small chiefs. A tie of friendship was the mutual exchange of their names. They practised the couvade. The Arawaks were armed with sword-clubs and javelins, hurled by means of ornamented spear-throwers. The chief weapon of the Caribs was the bow. The male prisoners were eaten. There is no evidence that stone weapons were used, the blades of stone found being tools. Charms were made of wood and stone, images of man and animals. Interesting are the stone collars which are said to be the translation into stone of originally a wooden hoop, a tree-fork bent and fixed by bandages into this shape. The enclosing of a spirit in such a circle is connected with tree-worship. Beautiful stone collars are found also in the Maya-Mexican countries.

But there is very little known about such and similar curiosities beyond the often gratuitous accounts of the old chronists, and the same applies to the beliefs and habits of these vanished people. Some are no doubt of genuine indigenous origin; others point to the western or to the southern mainland, just as one would expect. Since these islanders used dug-outs, large enough for even long voyages, it is not surprising that their kind of civilisation—as shown by their weapons, ornaments, stone masks, figurines, pottery, etc.—was more or less alike all over the archipelago.

## THE ABNORMAL PROPAGATION OF SOUND BY THE ATMOSPHERE.

MR. S. FUJIWHARA has recently published a second valuable memoir on the abnormal propagation of sound-waves in the atmosphere (Bull. Centr. Meteor. Observatory of Japan, vol. ii., 1916, pp. 1-82). As in his previous paper (NATURE, vol. xcii., 1914, p. 592), he ascribes the peculiarities investigated to variations of the air-temperature and of the velocity and direction of the wind, and he concludes that the structure of the upper atmosphere may be inferred from the form of the region of audibility.

The present memoir consists of two chapters. The first is theoretical, and deals with the modes of propagation of sound-waves through the atmosphere, the structure of which may be one of the five types observed by Capt. C. J. P. Cave at Ditcham Park, Petersfield, Hants. He shows that the region of audibility, including the sound-source (or proximate region), may in many cases be of triangular, or rather fish-tail, form, the axial direction of which may be not only in the direction of the wind then prevailing, but also in any other direction, at right angles or even opposite to that of the wind; for it depends chiefly on the direction of the wind in the lower stratum of the atmosphere with respect to that at the earth's surface. In other cases the proximate region may assume a spiral form, with the vertex at the source of sound and extending in the sense of the veering of the wind in the upper atmosphere. The regions of audibility due to winds at different heights may overlap one another. Detached regions of audibility may appear in a zone subtending an angle of less than two right angles at the sound-source, and they may be of any form. If the wind remains steady in direction and velocity in the upper layers, or if there is a decrease in velocity in the upper atmosphere, detached regions should not occur. With an increase of velocity in the upper atmosphere, detached regions may occur in the same direction as the proximate region. But if there should be a reversal or great change of direction in the upper layers, or if the upper wind should blow from a distant low-pressure centre with frequent reversal in the lower

Digitized by Google

layers, detached regions should be more often present than absent.

In the second chapter Mr. Fujiwhara compares his theoretical investigations with the results of sixty-five explosions during the years 1912 and 1913, for the most part those of the Asama-yama, in Central Japan. These show that the axis of the region of audibility may or may not agree with the direction of the wind at a moderate height; that in some cases the regions of audibility are triangular or spiral in form; that detached regions may occur on the same side of the source, while sometimes a very large detached region may be found in company with a very small one at the source; and, lastly, that detached regions of audibility and a silent region may appear in any direction and at any distance according to the prevailing condition of the weather. In Japan the monsoon exercises a powerful influence on the propagation of sound-waves in the atmosphere, and this accounts for the observed differences in summer and winter. In summer the formation of the detached region of audibility is rather common, and takes place towards the west or south-west of the source, while in winter the phenomenon occurs more rarely and is then caused by an approaching cyclone. C. DAVISON.

## *SIR LAUDER BRUNTON, BT., F.R.S.*

ON the 16th of the month this distinguished physician passed away after a long illness, borne with rare fortitude. Although retired from private practice, Brunton was far indeed from retirement in respect of those public causes to which, with the pious tenacity of his race, he devoted much of his life, and a fervour almost religious in its depth and constancy. Some weeks before his death the present writer had visited Lauder Brunton, and witnessed both the distress under which he laboured and the ingenious methods he had devised for keeping the evil at bay; not in the desire of a mere prolongation of life, though this indeed were no unworthy intention, but in order to cherish the fire of its last embers for those humane ends which he had so ardently at heart. It was therefore with admiration that, about three weeks before his decease, the writer received from his friend now silent a long and important letter covering certain documents and proposals on the subject of physical education, a movement to which, in his later years, Brunton had given no little energy and guidance, especially for the sake of children and young people, and which he was pressing forward almost with his latest breath. pure of all self-seeking. Although these great teachers were not quite alike in the ways of their medical observation, yet to the particular skill of each were added kindliness of heart and an earnest sympathy which won the confidence of the sufferers who sought their aid. If Brunton had not the imposing personal presence of certain eminent physicians of the past, no one could speak with him without being affected by his gentle, persuasive enthusiasm, and that faith in his art and in mankind which engendered alike faith and hope in those who only too often sorely needed these blessings.

Lauder Brunton was one of the first of the scientific practising physicians who used no empirical remedies without seeking to discover their mode of action, and by pharmacological and other research endeavoured to add to their number. Bence Jones, Golding Bird, Pavy, were of the generation before him, it is true; but few physicians whose interests before all else were, and still remained, clinical, had likewise followed scientific investigation so systematically and in so disinterested a spirit. Moreover, in his particular departments of science Brunton was a pioneer, especially in pharmacology and in the physics of the circulation. With a mind strengthened by the seriousness and philosophical temper of his great university of Edinburgh, Brunton, after graduation, spent two or three years in foreign study, for the most part in Germany; and no British physician had a better knowledge than he of German teachers, German industry, and of that necessary condition—the German tongue. Thus for him the war was full of sadness.

In this brief tribute no attempt can be made even to indicate the character and extent of Brunton's scientific work, pharmacological, clinical, and hygienic. His contributions are only partially presented, indeed, in the two or three portly octavos in which many of them were recently reprinted. But if to the chief or to the more familiar of his works some allusion may be made, it would be to his researches with Fayrer into venoms—a successful attempt to clarify a very ancient and chequered story, as the historian of medicine well knows; to his part as one of the Commission which reported on Pasteur's treatment of hydrophobia; to his services on the Hyderabad Commission on the effects of chloroform, by which, if its results were doubted in some quarters and in others enlarged, nevertheless the whole problem was raised to the plane of its infinite importance; to his work on tuberculosis, which was informed by the spirit of a

Digitized by Google

the use of a graphic curve which betrayed the inadequacy of the sphygmograph to follow the finer movements of the artery, yet how many brilliant discoveries have arisen from accidents of manipulation or interpretation! To have discovered the means of controlling one of the most cruel ills to which man is subject is perhaps the laurel wreath amid the many memorials of one who, in his humanity, would have prized this above all rewards.

By academic and official decorations Lauder Brunton was richly distinguished; but perhaps, in his loyal and patriotic heart, the honour of none of these was to be compared with the glory of his younger son, a promising Cambridge medical graduate, who last year gave his life on the field of battle for his country—a glory, but also a sorrow which, falling but a brief five years after Lady Brunton's death, deepened the shadows of his latter days. Happily his elder son, also on military service, and his devoted daughters were still spared to him. C. A.

---

The death of Sir Lauder Brunton on September 16, in his seventy-third year, has deprived the world of a great physician, and brought sorrow to a wide circle of friends. Largely by his vivifying studies and teaching, pharmacology has become a definite branch of science. Practical medicine depends on physiology, pharmacology, and pathology, and all three tend more and more to become subdivisions of the all-embracing science of chemistry. In no departments of the healing art is the influence of laboratory methods more apparent than in those directed to the study of disorders of digestion and diseases of the circulation; and in both these directions Sir Lauder Brunton was a pioneer worker. He had the clearest conceptions of clinical facts, and possessed to an unusual degree the practical quality of being able to apply extensive knowledge of physiological medicine to the work of the hour. His stimulating personality will be widely missed by his professional brethren as well as by many who have benefited by his work and advice.

Thomas Lauder Brunton was born at Hiltons Hill, Roxburgh, in 1844, and received his medical training at the University of Edinburgh, where he had a distinguished academic career, and graduated M.B., C.M. with honours in 1866, receiving also the gold medal for his thesis. In the following year he became B.Sc., in 1868 he obtained the M.D., and two years later the D.Sc., in the meanwhile having also studied at Paris, Vienna, Berlin, and Leipzig. Settling in London, he became lecturer on materia medica at the Middlesex Hospital in 1870 and assistant physician at St. Bartholomew's Hospital in 1875, to which school he remained attached as lecturer, physician, and consulting physician.

Early in his career Brunton's inclinations leaned towards the scientific side of medicine, and composition of the blood, and on the actions of the two drugs, digitalis and mercury.

Brunton's post at St. Bartholomew's carried with it the lectureship on materia medica and therapeutics, and he turned his attention to the effects of medicines and instituted many experimental investigations on the actions of drugs upon himself and upon animals. In 1885 he published his well-known book on "Pharmacology, Materia Medica, and Therapeutics," which passed through many editions in this country and abroad. This appeared at an opportune moment, and largely owing to his work and writings pharmacology became separated from materia medica and established as a branch of physiology.

In 1886 he was appointed a member of the Commission to report upon Pasteur's system of inoculation for hydrophobia, and in 1889 a member of the Nizam of Hyderabad's Chloroform Commission. For the latter a considerable amount of experimental work was carried out and a valuable report issued, though no very definite conclusions as to the action of chloroform were arrived at. In the meantime, Brunton had become one of the best-known consulting physicians in the country, and in the art of treatment he was most resourceful. He introduced a new class of remedies, the vaso-dilators, into medicine, and by the use of amyl nitrite for angina pectoris was the first to employ a remedy because its physiological action was opposed to the pathological condition existing in this disease, viz. rise of blood-pressure.

In 1900 he was knighted, and nine years later was given a baronetcy, and he was the recipient of many honours from universities and societies at home and abroad. He was also Gulstonian and Croonian lecturer and Harveian orator of the Royal College of Physicians of London. Several works emanated from his pen, notably the "Introduction to Modern Therapeutics," illustrating the connection between the chemical structure and physiological action of drugs, "Disorders of Assimilation," and "Therapeutics of the Circulation."

Sir Lauder Brunton, outside his professional work, was keenly interested in all schemes in favour of national health, of school hygiene, of physical culture and military training, in the furtherance of which he gave bountifully of his time and energies.

---

## NOTES.

GEOLOGISTS will regret to hear of the death of Mr. R. J. L. Guppy at his home in the island of Trinidad on August 5, and within a few days of celebrating his eightieth birthday, Mr. Guppy having been born in London on August 15, 1836. In early life he qualified as a civil engineer, and afterwards travelled through Australia, Tasmania, and New Zealand. On joining his family in Trinidad in 1859, he took part in the construction of the Cipero Rail-

Digitized by Google

membered for his researches on the geology of Trinidad and the other West Indian islands. On this subject he contributed upwards of fifty papers, several of which were published by the Geological Society of London. He accumulated a great knowledge of the Tertiary faunas of that region, and did much towards rendering a correlation of the various horizons represented. His earlier memoirs dealt with the San Fernando deposits of Trinidad containing Orbitoidal and other fossils, which at first he regarded as of older Miocene age, but which afterwards he more correctly assigned to the younger Eocene or Lower Oligocene. He was always an ardent student of natural history, being particularly interested in the recent and fossil mollusca, and was also an authority on the rich deposits of petroleum which have made Trinidad so famous. Some years ago he was instrumental in acquiring for the British Museum the second largest known Pleurotomaria, possessing a height of 150 millimetres, which was discovered off the island of Tobago. Mr. Guppy was a corresponding member of the Zoological Society of London, and of the New York and Philadelphia Academies of Science. He had served as president of the Scientific Association of Trinidad, and was the first presiding officer of the Royal Victoria Institute Board. Much work yet remains to be accomplished among the Tertiary rocks of Trinidad, as many of the geological horizons are still in confusion and imperfectly understood; but whatever is attempted in the future, there is no doubt that Mr. Guppy's valuable memoirs will always furnish us with an important basis for later investigations on so interesting a subject.

MR. E. G. KENSIT, who fell in action at Delville Wood on July 17, was a great-nephew of the late Dr. Harry Bolus, and became a member of the staff of the Bolus Herbarium in the Botanical Department of the South African College in 1912. In August, 1915, he enlisted in the South African contingent for service overseas. After a period of training at Potchefstroom, he was sent to Egypt, and served through the Senussi campaign. The circumstances of the death are described in the following extract from the *Cape Times* of August 30:—"On the colonel of his regiment calling for a volunteer for the purpose of reconnoitring the enemy's line and securing certain information, Kensit was among those who stepped forward, and his offer was accepted. He was seen to be hit as he crawled away, but he continued with his task, and after an interval crept slowly back, hampered by his wound. On reaching the parapet he was assisted to surmount it. He was able to give the officer all the information that was wanted, but he had no sooner done so than he rolled over—dead."

WE regret to learn that Mr. Gustav Mann died at Munich on June 22, in his eighty-first year. To him we owe our knowledge of the botany of the Cameroon Mountain, for he was the pioneer of botanical exploration in this region when he was attached to Dr. Baikie's Niger Expedition in 1859 as botanical collector for Kew. He ascended Clarence Peak, in Fernando Po, and made extensive collections of plants from the mountains of western tropical Africa, which have been described in papers presented to the Linnean Society. He then went out to India, and after serving for a year as assistant in the Government cinchona plantations was transferred in 1864 to the Bengal Forestry Department. From 1868 he served in Assam, and in 1882 was appointed Conservator of Forests, which position he held with distinction until his retirement in 1891.

WE learn from the *British Medical Journal* that Lieut.-Col. G. M. J. Giles, Bengal Medical Service (retired), died at Plymouth on August 24, aged sixty-two. In his early service he spent some years as surgeon naturalist in the Indian survey ship, the Royal Indian Marine steamer *Investigator*, and in 1886–87 accompanied the late General Sir William Lockhart on an exploring expedition in the Pamirs. He was the author of works on kala-azar and beri-beri, mosquitoes, climate and health in hot countries, and tropical climatology.

A FEDERATION of British Industries has been formed to provide a body capable of representing the interests of the British manufacturing and producing industries. The objects of the federation may be summed up briefly as the organisation and development of industry now and after the war, in co-operation with labour and in conjunction with the Government and Government departments. The federation will at once concern itself with the reconstruction of British trade after the war; the development of sources of supply of raw materials; and questions arising out of the transition from war to peace, such as measures to mitigate possible unemployment during that period. Every effort is to be made to ensure that in future no important action affecting British industry shall be taken by the Government without due weight being given to the views of manufacturers. A condition of membership is an annual subscription of 100*l*. a year, with an obligation to continue such subscription until June 30, 1919. Mr. F. Dudley Docker, C.B., is the president of the federation.

THE recently issued report (Cd. 8346) of the Committee on Financial Facilities for Trade to the President of the Board of Trade recommends the establishment of a British Trade Bank, constituted under Royal Charter, to fill the gap between the home banks and the Colonial and British-foreign banking houses, and to develop facilities not provided by the present system. It is proposed that the bank should have a capital of 10,000,000*l*., and should, among other activities, inaugurate an information bureau, co-operate with merchant and manufacturer, and become a centre for syndicate operations. The bureau, it is suggested, should be independent of the Commercial Intelligence Branch of the Board of Trade, and would not necessarily deal only with schemes in which the bank proposed to take financial interests, but might be made a centre for the investigation of other projects. The report urges that if financial assistance is given by the Government to undertakings in connection with what are known as "key" industries, the business should be done through the new bank. The committee thinks that such a bank would, with efficient management, not only be a great boon to British trade, but also should prove a commercial success.

AN important addition to the art collections of the Philadelphia Museum is reported in the Museum Journal for last March. Mrs. Dillwyn Parrish, of London, has presented five Roman mosaics in memory of her late husband. Of these, the two most interesting specimens from the point of view of size come from Carthage; the other three, smaller, but charming, examples, are said to have been obtained in Rome. The Carthage mosaics are examples of *opus vermiculatum*—cubes of marble or other material disposed so as to attain to a pictorial effect. One of the Italian pieces, representing a duck, has much in common with some of the mosaics found in the House of the Faun in Pompeii. Another, considerably later in date, represents two griffins facing an urn, and is an example of the stiff, conventional, unimaginative work of the second century A.D. On

Digitized by Google

the other hand, the lack of imagination is in some degree made up by the great technical skill shown in the treatment of the griffins, the colour being obtained by the use of cubes of opaque glass applied to the wings and tongues of the beasts.

THE deficiencies of modern India in the matters of house building and sanitation are a cause almost of despair to the authorities. No problem is so difficult as that of sanitation, because the official runs the constant risk of offending some religious or social prejudice. But it is not because their own writers have neglected the subject that the present condition of things has arisen. In the June issue of the Journal of the Bihar and Orissa Research Society Dr. Mahamahopadhyaya Ganga Nath Jha has collected the ancient Sanskrit laws on the subject. They deal with the sanitation of houses, and provide minute directions on the right uses of food and drink. Much of this is, no doubt, academic, and the rules on these subjects are the speculations of philosophers which in many cases could not have been brought into actual practice. But many of them are judicious, and may help the officer of health in preaching the value of sanitation. The pandit ends by saying:—"From the above it will be seen that the old people of this country knew and practised many laws of health and sanitation which have been forgotten, with results that all deplore."

THE *Indian Journal of Medical Research* for July (vol. iv., No. 1) contains several important papers. Dr. Soparkar describes a method for cultivating the tubercle bacillus from sputum after destruction of adventitious micro-organisms by treatment with caustic soda. Dr. Agnes Scott writes on osteomalachia, and Major McCarrison, I.M.S., describes the successful experimental production of congenital goitre in goats by feeding them with cultures of micro-organisms grown from the fæces of goitrous individuals (goats). He concludes, therefore, that congenital goitre is due to the action on the fœtal thyroid of toxic substances derived from the maternal intestine.

ON July 29, 1915, the Government passed the Milk and Dairies (Consolidation) Act, 1915, which consolidated in one Act the 1914 Bill and previous Acts of Parliament. The Act, however, does not come into force until such date as the Local Government Board may by Order appoint. As the Bill was passed by mutual consent of all sections of both Houses, it cannot be expected to include far-reaching improvements in the milk supply. It does, however, provide that the Local Government Board may issue "Orders," upon which the success of the Act will almost entirely depend. With the view of defining what may be considered the requirements necessary to improve the milk supply, representatives of the National Clean Milk Society, the Society of Medical Officers of Health, and the Sanitary Inspectors' Association have formulated a series of recommendations which have been forwarded to the President of the Local Government Board, and a copy of which we have received. These recommendations have been conceived in a moderate spirit, and their adoption would do much to improve the general milk supply. They do not, however, include a clause prohibiting the addition of skimmed milk to milk, a matter of some importance.

BEFORE the war the United States imported annually from Germany [illegible]

of California will suffice to furnish all the future needs of the country, and large quantities are already being placed on the market from this source. But, according to *California Fish and Game* for July, fears have been expressed that the cutting of the kelp will have an injurious effect upon the fisheries of the State, and this because of the protection afforded by the weed to the beaches, and the danger of exterminating the clams and spiny lobsters which live more or less within the protection of the kelp. They also fear that the young fish, especially barracuda, which are in the habit of seeking refuge here, will be driven away, and further that such fish as spawn here will similarly be destroyed. These several objections have now, however, been carefully examined, and it is pointed out that the kelp-cutters, or reapers, do not cut below 6 ft., thus leaving ample shelter. It may be, indeed, that the cutting will prove actually beneficial, since it will be less easily torn up by storms. The species of kelp which is thus being harvested is *Macrocystis pyrifera*, a plant which ranges in length from 100 to 300 ft.

IN the *Journ. Agric. Research* (vi., No. 14) Mr. V. L. Wildermuth describes the life-history of a lacewing fly (*Chrysopa californica*). The larvæ of Chrysopa are well known as beneficial insects on account of their habit of feeding on "greenfly" (aphids). *C. californica* lives as a larva for about sixteen days, during which it undergoes two moults, and eats from 74 to 160 full-grown aphids, besides a still larger number of young ones.

AN excellent twenty-page pamphlet by the Rev. Jas. Waterston on "Fleas as a Menace to Man and Domestic Animals" forms No. 3 of the British Museum's Economic Series. The structure and life-history of the insects are described in sufficient detail, and readers are warned of the great danger to be feared from those species which act as carriers of the plague-bacillus between rats and human beings. There are many instructive and illuminating statements, such as an observation quoted from Prof. Osborn, who once collected a teaspoonful of fleas' eggs from the dress of a lady who had been fondling a kitten!

IN the *Entomologists' Monthly Magazine* for August Mr. E. Meyrick publishes a "Note on Some Fossil Insects," dealing particularly with a hindwing, of Upper Triassic age, from Queensland, which has been named *Dunstania pulchra* and referred to the Lepidoptera by Mr. R. J. Tillyard. Mr. Meyrick points out that the nervuration of this hindwing would indicate a highly specialised Lepidopteran type, if the insect to which it belongs were really a moth. As the wing further possesses a corneous margin "altogether abnormal, no other Lepidoptera showing a trace of it," he is inclined, though with some hesitation, to suggest that it must be referred to a Homopterous insect. Incidentally he supports the Lepidopteran nature of Butler's *Palaeontina oolitica*, emphasising its affinity to the family of the "swift-moths" (Hepialidæ).

THE annual report of the Dove Marine Laboratory for 1916 contains an important paper by Prof. A. Meek on the method of estimating the age of fishes by inspection of the annual growth-rings on the scales. This method was extended by Lea, Dahl, and Hjort some years ago in this way: Assuming that the growth-rates of the scale and body of the fish (the herring) are strictly proportional, it ought to

Digitized by Google

were criticised by Miss Rosa Lee, of the English Board of Agriculture and Fisheries. It appeared as if there was a contraction of growth of scale relative to the growth of the body, and the Norwegian investigators sought to explain this by postulating elimination of the fish exhibiting the more rapidly growing scales. In the publication now noticed Prof. Meek shows that there is not exact correlation between growth of body and of scale; the latter grows at first less rapidly than, then at the same rate as, and finally more rapidly than does the body. Curves of growth are probably exponentials and show this imperfect proportionality. Selection does indeed take place; there is a tendency (in the case of the herring) for fish of the same phase of sexual maturity to shoal together, so that those which are (sexually) younger tend to join with shoals of their own phase, and *vice versâ*. In the same publication Mr. B. Storrow applies the principle to the growth-rate of other fishes.

PROF. E. W. SINNOTT contributes to the *American Naturalist* (l., No. 596) an essay on the "Comparative Rapidity of Evolution in Various Plant Types." He concludes that the most recently evolved members of the North Temperate flora are herbaceous in habit, that herbs tend to be grouped in fewer and larger genera and families than shrubs and trees, and that herbs, with their rapid multiplication of generations, must be "in most cases undergoing evolutionary development much more rapidly than are trees and shrubs." The most ancient Angiosperms were probably woody, and "herbaceous vegetation has made its appearance in comparatively recent geological time."

IN his history of Ethiopian earthquakes (*Boll. Soc. Sismol. Ital.*, vol. xix., pp. 293–350) Prof. L. Palazzo has added to our knowledge of the seismic regions of Africa. His catalogue, which closes with the year 1912, contains 142 entries, all but seven since the beginning of the nineteenth century. He shows that the seismicity of Erythræa is higher than was supposed, and that the earthquakes sometimes attain a destructive intensity, while those which occur near the coast are occasionally accompanied by sea-waves. As to their origin, some are purely volcanic, but the majority he classes under Mercalli's heading of perimetric or intervolcanic.

DR. A. CAVASINO has recently published a valuable memoir on the after-shocks of the Italian earthquake of January 13, 1915 (*Boll. Soc. Sismol. Ital.*, vol. xix., 1915, pp. 219–91). These were recorded at the geodynamic observatory of Rocca di Papa, which is about forty miles from the epicentral area. The earthquake occurred at 7.53 a.m., and, owing to the strength of the shock, all the seismographs in the observatory were suddenly thrown out of action. Within three-quarters of an hour the more sensitive instruments were repaired, including the Agamennone microseismometrograph, the records of which are here considered. The loss of the earlier records of after-shocks is of little consequence, for, at Rome, the seismogram of the principal earthquake obliterated those of the after-shocks, and, moreover, the ground during the first hour was in such a state of continual agitation that individual shocks could not be distinguished. The number of after-shocks registered during the first twenty hours was 302, and during the first six months 1280. Dr. Cavasino considers that the distribution in time of these after-shocks does not follow Omori's well-known law deduced from the after-shocks of the great Japanese earthquakes.

THE Geologists' Association (Proc., vol. xxvii., 1916, p. 1) publishes a beautifully illustrated paper by Prof. Garwood on "The Faunal Succession of the Lower Carboniferous Rocks of Westmorland and North Lancashire," which serves, with its maps, as a guide to a very attractive district, including the high moors of Shap and the picturesque fault-blocks of the Arnside shore. In the same volume (p. 79) Mr. P. G. H. Boswell describes the constitution of the North Sea drift as found across eastern England. His mechanical analyses usefully distinguish this drift from the later Glacial brick-earths; but why does he use such expressions as ½ and 1/100 of a millimetre? The remarkable variety and beauty of the mineral fragments in this mixed material are pointed out by one who clearly loves his subject.

THE "Rainfall of India" for 1914, which is the twenty-fourth year of issue, is collected from the returns published by the various Provincial Governments, and is issued in one volume by the Meteorological Department of the Government of India under the superintendence of Dr. G. C. Simpson, officiating Director-General of Observatories. The volume gives the monthly and annual rainfall, as well as the average rainfall for about 3000 stations in India, from the records taken daily at 8 a.m. The number of rainy days is given, and although the rainfall is measured to hundredths of an inch, a "rainy day" is taken as that on which a tenth of an inch or upwards has fallen, and the normal number of rainy days given in some cases is also calculated on the same assumption. The value of a "rainy day" being ten times as great in India as in England is regrettable, and some adjustment may be found possible when a change is made to meet the registration by the new units of measurement now generally adopted in this country and elsewhere. The normals used for the comparison are those revised to 1910 for the whole of India, and are mostly for at least thirty or forty years.

THE Bureau of Standards of the Department of Commerce of Washington issues a Scientific Paper, No. 286, on "The Determination of Aluminium as Oxide." The author, Mr. William Blum, finds that, to avoid loss of alumina, a hot 2 per cent. solution of ammonium chloride should be used for washing the precipitate, as this facilitates coagulation. Methyl red is used as an indicator of the optimum condition of alkalinity, since it shows a sharp colour change at the desired point. The quantitative reasons for its selection are interestingly stated. The elimination of other substances from the precipitate is considered. A copy of the paper will be sent free on application to the Bureau of Standards.

THE new American journal, *Aviation and Aeronautical Engineering*, contains much of interest, and should prove a successful enterprise, both in the States and elsewhere. The second number is specially worthy of note on account of the scientific nature of the contents. There is an excellent article on "Aviation and Aerography," in which the importance of meteorological research as a help to aviation is strongly emphasised. A short note entitled "An English Photograph of Great Interest" shows a very keen appreciation of the merits of the Royal Aircraft Factory machines, and of their inherent stability. An article on "Steel Construction of Aeroplanes" contains an account of a method of construction which must eventually supersede wood for the larger machines. Perhaps the most interesting item from a scientific point of view is the second part of "A Course in Aerodynamics and Aeroplane Design," written from the Massachusetts Institute of Technology. The authors treat of the elements of aerodynamical theory, and if future articles of the series are as clearly

Digitized by Google

written as that in the present number, they should prove of considerable value to those who need an introduction to the subject.

FROM the reports of the behaviour of the recording instruments at a number of magnetic observatories in different parts of the world during the solar eclipse of August 21, 1914, Dr. Bauer and Mr. Fisk, of the Department of Terrestrial Magnetism, Washington, have drawn some preliminary conclusions as to the effects of eclipses on solar terrestrial magnetism, which will be found in the June number of *Terrestrial Magnetism and Atmospheric Electricity*. At stations from which the eclipse was visible it appears to have changed slightly the daily march of the declination needle. At four British and Danish stations for which curves of the daily change of declination are given the normal motion of the needle to the west was arrested, and in some cases reversed, a short time before totality of the eclipse. Outside the region of visibility of the eclipse no magnetic effects were observed. These results appear to justify more extensive preparations for observing the effects of the solar eclipse due June 8, 1918.

MESSRS. KODAK, LIMITED, have issued a new and much improved edition of their "Wratten Light Filters" (1s.), in which they describe some ninety colour screens. Of those previously catalogued eleven are omitted and twenty-nine new filters are introduced, the latter including a series of nine made to equalise the tints of various artificial lights for facilitating photometric work. The transmissions of nearly all the filters are given in very clearly expressed curves, a vast improvement on the reproductions of spectrographs taken with a graduating wedge in front of the slit, as given in the previous editions. For those who need more exact data the actual readings obtained by the use of the spectrophotometer are given in copious tables, and will prove of great value. "The Photography of Coloured Objects," another of Messrs. Kodak's publications, has been revised, and now includes "Orthochromatic Filters," which was until now published separately. For the benefit of any who do not know this volume, we may say that it gives a clear and accurate account of the principles involved, and points out objects of many kinds that are really "coloured," though they do not appear to be.

## OUR ASTRONOMICAL COLUMN.

ENCKE'S COMET.—Prof. Strömgren reports that Encke's comet was observed by Dr. Max Wolf on September 22. At 9h. 41·5m., Königstuhl mean time, its position was R.A. 22h. 28m. 39s., declination 7° 8′ 5″ S. The magnitude of the comet was 16·5.

THE NEBULA H II. 78 LEONIS.—It is interesting to note that Mrs. Isaac Roberts is continuing her detailed studies of nebulæ photographed at Crowborough by the late Dr. Isaac Roberts. The subject of a recent paper (Monthly Notices R.A.S., vol. lxxvi., p. 647) is the nebula H II. 78 Leonis (N.G.C. 3367), photographed in 1902. The nebula extends for about 2′ from north to south, and 2·5′ in the direction at right angles, and is described as a left-hand spiral with a bright stellar nucleus. The nucleus is encircled twice by the spiral arm, which shows numerous condensations. With the aid of the Roberts "pantograver," measures were made of many of the bright nebulous knots, and of nineteen stars which appear in the neighbourhood of the nebula. All the measured objects are clearly indicated in a key chart, and the tabulated data will doubtless be of considerable value in subsequent investigations of relative motions within the nebula.

PHOTOGRAPHS OF MARS.—In the September number of the *Observatory* an account of a minute examination of photographs of Mars taken at Flagstaff by Dr. Lowell and his co-workers is given by G. H. Hamilton. The photographs were studied without reference to maps of the planet, and details common to three or more of the images, of which there were sometimes as many as four dozen on a single plate, were inserted in sketches. Subsequent comparisons in all cases showed a very close agreement with the accepted maps in the observatory. One of the sketches, from photographs taken on March 15 of the present year, is reproduced, and shows an abundance of detail, including numerous canals. Mr. Hamilton is of opinion that the linear character of the canals, as represented by Dr. Lowell, is completely confirmed by the photographs. By the use of a finely divided transparent scale, it was found possible to obtain satisfactory measurements of the positions of the principal markings, due allowance being made for halation.

SPECTRUM OF THE NEBULA H IV. 39 ARGÛS.—An account of the spectrum of H IV. 39 Argûs (N.G.C. 2438) has been given by Dr. Max Wolf (*Sitz. Heidelberg Akad. d. Wiss.*, March, 1916). The spectrum was photographed at the Königstuhl Observatory, Heidelberg, on February 20, with an exposure of five hours. The nebula is very faint, and direct photographs show it to be of annular form with an eccentrically situated stellar nucleus; the eastern side of the ring is the brighter, and the nucleus lies nearer the western edge. The spectrum is almost identical with that of the ring nebula in Lyra, but much fainter. In order of brightness the lines are λ 373, 387, 434 ($H_7$), 469, 501, and 397; there is possibly also a faint line at 352. As in the Lyra nebula, a distribution of the different gases in layers is indicated by the varying distances to which the lines extend. The line 373 reaches furthest outwards, but has a marked minimum in the interior of the ring. The lines 387 and 434 reach further towards the centre; and, in striking contrast with the other lines, 469 (*i.e.* 4686, of "proto-helium") is brightest within the ring, and extends only a small distance from the nucleus.

## THE UNITED STATES NATIONAL RESEARCH COUNCIL.

AN account of the inauguration and organisation of the National Research Council of the United States was published in our issue of August 3 last (vol. xcvii., p. 465), and the article pointed out that from the cordial interest shown by all who had learnt of the work in its early stages, it was evident that so soon as a widespread request for co-operation could be extended it would meet with general acceptance. A preliminary report of the Organising Committee to the president of the U.S. National Academy of Sciences, published in the August issue of its Proceedings, shows that this expectation has been justified, and some of the first instances of co-operation are given. Prof. G. E. Hale, chairman of the committee, has also sent to the *New York Times* an account of what is being done in the United States to mobilise science for industrial progress and military efficiency, and we reprint his letter below. It will be seen that the president of the Throop College of Technology in Pasadena, California, an institution which gives special attention to research, hearing of the plans of the Research Council, offered the assistance and co-operation of the recently endowed research laboratory of chemistry, and secured at once an additional endowment of 20,000*l.* for scientific research. In somewhat similar circumstances a gift of 100,000*l.*

Digitized by Google

has been made to the Massachusetts Institute of Technology, with the expectation that much of the income will be used for research. A resolution of the New York Engineering Foundation expresses approval of the co-ordination and federation of the research agencies of the United States undertaken by the National Academy, and also willingness to assist. The foundation has offered its entire income for the coming year—including a special gift of 1000*l*.—towards the expenses of organisation and to provide a New York office for the council. Resolutions of a similar kind are to be proposed to other scientific societies in the States.

---

At its annual meeting in April the National Academy of Sciences volunteered to organise the scientific resources of educational and research institutions in the interest of national preparedness. This offer, which was immediately accepted by President Wilson, has led to the establishment of the National Research Council.

Public welfare and national security depend upon industrial progress and military efficiency; and these, in turn, result from practical applications of scientific knowledge. A superstructure, no matter how perfect, must have firm foundations, and thus the development of our industries must go hand in hand with the advancement of knowledge through research.

It is equally true that the mobilisation of industry, so successfully undertaken by the national engineering societies in co-operation with the Naval Consulting Board, must be accompanied by the mobilisation of science. This necessity has been recognised in England by the establishment of an Advisory Council for Scientific and Industrial Research, and in Australia by the organisation of a National Institute of Science and Industry. Thus it is expected ultimately to overcome the telling advantages, both in war and in peace, which Germany has long enjoyed because of the organisation and development of her scientific resources.

Paul Deschanel has remarked of French men of science: "Ils pensent que défendre la vérité est le meilleur moyen de servir la patrie." Thus the duties of a National Research Council should not be confined to the necessities of war or the development of American industries. We should recognise, with Carty, the engineer, that when adapted to practical uses the "results of the pure men of science become of incalculable value to the industries as a whole." And we should not fail to perceive that every form of scientific research contributes to human progress.

Euclid, working out problems in pure mathematics in Alexandria, prepared the way for the calculations of the engineer. Galileo, discovering the satellites of Jupiter, convinced the world of the truth of the Copernican theory, broke down absurd medieval conceptions which prevented scientific progress, and stimulated exploration and advance in every field. Pasteur, studying the optical properties of certain crystals with no thought of practical result, was led to his investigations of bacteria and his epoch-making discoveries for the benefit of mankind.

Thus scientific research in any field, whether for

by Act of Congress, which stipulated that "the academy shall, whenever called upon by any department of the Government, investigate, examine, experiment, and report upon any subject of science or art. . . ." During the war, and frequently in later years, the academy has been consulted by Congress, by the President, and by various members of his Cabinet. It is thus the agency naturally chosen for the organisation of the National Research Council.

The purpose of the council is to bring into co-operation existing governmental, educational, industrial, and other research organisations, with the object of encouraging the investigation of natural phenomena, the increased use of scientific research in the development of American industries, the employment of scientific methods in strengthening the national defence, and such other applications of science as will promote the national security and welfare.

The council will be composed of leading American investigators and engineers, representing the Army, Navy, Smithsonian Institution, and various scientific bureaus of the Government; educational institutions and research foundations, and the research laboratories of industrial and manufacturing establishments.

Research committees of two classes will be appointed:—

Central committees, dealing with various departments of science, comprised of leading authorities in each field, selected in consultation with the president of the corresponding national society.

Local committees in universities, colleges, and other co-operating institutions engaged in scientific research.

The organising committees will recommend to the National Research Council the following plan of procedure, approved by the council of the National Academy, but open to such modification as the Research Council may deem desirable:—

(1) The preparation of a national census of equipment for research, of the men engaged in it, and of the lines of investigation pursued in co-operating Government bureaus, educational institutions, research foundations, and industrial research laboratories; this census to be prepared in harmony with any general plan adopted by the proposed Government Council of National Defence.

(2) The preparation of reports by special committees, suggesting important research problems and favourable opportunities for research in various departments of science.

(3) The promotion of co-operation in research, with the object of securing increased efficiency; but with careful avoidance of any hampering control or interference with individual freedom and initiative.

(4) Co-operation with educational institutions, by supporting their efforts to secure larger funds and more favourable conditions for the pursuit of research and the training of students in the methods and spirit of investigation.

(5) Co-operation with research foundations and other agencies desiring to secure a more effective use of funds available for investigation.

(6) The encouragement in co-operating laboratories of researches designed to strengthen the national defence and to render the United States independent of foreign sources of supply liable to be affected by war.

Digitized by Google

and utilise new methods of preventive medicine for the protection of troops in the field.

Organic Chemicals, appointed in co-operation with the American Chemical Society, to secure co-operation among chemists in researches required for the manufacture of dyestuffs, synthetic medicinals, and other chemicals made scarce by the war.

Communications, appointed in co-operation with the American Physical Society and the American Institute of Electrical Engineers, to develop and apply the most effective devices for military communications, the detection of submarines, and other similar purposes.

Committees for the promotion of research in applied mathematics, astronomy, physics, chemistry, botany, zoology, and various other branches of science will also be organised by the council.

The most cordial spirit of co-operation has been shown by every individual and institution hitherto invited to take part in the work. Universities, research foundations, and industrial laboratories, in the event of war, would place every facility at the disposal of the Government. In times of peace they will co-operate with the council in the advancement of research. The Engineering Foundation, under the auspices of the United Engineering Societies, has passed resolutions commending the purposes of the council, and offering it a New York office in the Engineers' Building and the services of an executive secretary. Substantial contributions to a general expense fund have already been received. It is evident that so soon as a general request for co-operation can be issued it will meet with the widest acceptance.

Throop College of Technology, in Pasadena, Cal., has recently afforded a striking illustration of one way in which the Research Council can secure co-operation and advance scientific investigation. This institution, with its able investigators and excellent research laboratories, could be of great service in any broad scheme of co-operation. President Scherer, hearing of the formation of the council, immediately offered to take part in its work, and with this object he secured within three days an additional research endowment of 100,000 dollars. The spirit of national service and the increased appreciation of the value of science, which have resulted from the European war, should lead to many similar gifts elsewhere.

The following letter from the President shows his approval of the council's plans and his active assistance in completing its organisation :—

"Dr. William H. Welch, President of the National Academy of Sciences, 807 St. Paul Street, Baltimore, Md. :—

"My Dear Dr. Welch,—I want to tell you with what gratification I have received the preliminary report of the National Research Council, which was formed at my request under the National Academy of Sciences. The outline of work there set forth and the evidences of remarkable progress toward the accomplishment of the object of the council are indeed gratifying. May I not take this occasion to say that the departments of the Government are ready to co-operate in every way that may be required, and that the heads of the departments most immediately concerned are now, at my request, actively engaged in

## THE GOVERNMENT CINCHONA PLANTATIONS IN BENGAL.

THE fifty-fourth annual report of the Government Cinchona Plantations and Factory in Bengal for the year 1915–16 is as interesting and valuable a document as that for 1914–15 noticed in these columns last year. In the previous report the scientific side of the work for the past ten years was reviewed, while in that now under notice a review of the financial side of the operations for the past sixteen years is given. Since April, 1900, to March, 1916, the total expenditure amounted to 42,65,600 rupees and total receipts to 39,30,000 rupees. The deficit of 3,35,600 rupees is, however, not a sign of financial mismanagement, but is an indication of remarkable and highly successful administrative ability. The deficit was incurred within the period 1905–14, during which time the department was being greatly improved. The explanation, which is simple, is given in the words of the report, as the excellent work which is being done by Major Gage and his staff is deserving of wider recognition.

"About the beginning of the 1905–15 period it was seen that the demand for quinine—since 1892 in excess of the yield from plantation bark—was exceeding the factory output capacity, and that as more than 90 per cent. of the world's supply of bark and quinine was in the hands respectively of Java planters and about a dozen manufacturers, the risk of the formation of a 'Trust' and the abolition of an open market was not to be taken lightly. It was foreseen that, if while there was still an open market large quantities of bark and quinine were purchased at the lowest rates ever touched, it would allow the formation of a reserve of quinine large enough to meet the increase in demand and to serve as a stand-by in case of a severe malarial epidemic, what time the plantations were being extended on a scale large enough to render the department independent of external supplies and prices.

"So during 1908–14 large sums were expended on purchase of bark and quinine at very low rates and on extra extensive plantations. Subsequent developments have thoroughly justified the then heavy expenditure. For instance, if the annual quinine yield from the plantations had remained at its 1905 figure of 9000 lb., Government would have had to pay during 1913–15 at least 7,74,000 rupees in purchase of enough bark or quinine to make up the quantity (74,000 lb.) distributed during these years, whereas it cost Government to make the quantity required above the 1905 output level less than 3,08,000 rupees. In those two years alone Government saved at least 4,66,000 rupees, which exceeds the deficit for a period of sixteen years. The deficit will speedily be replaced by a surplus yearly increasing, and meanwhile it is covered many times over by readily realisable assets."

These assets include (1) additions to factory and machinery that have quintupled its 1900 output capacity; (2) 2418 acres afforested with timber and fuel trees; (3) 2295 acres planted with cinchona 7,69,085 rupees in value; (4) a reserve of 165,000 lb.

# THE BRITISH ASSOCIATION AT NEWCASTLE.

## SECTION A.

### MATHEMATICAL AND PHYSICAL SCIENCE.

OPENING ADDRESS (ABRIDGED) BY PROF. A. N. WHITEHEAD, SC.D., F.R.S., PRESIDENT OF THE SECTION.

### *The Organisation of Thought.*

THE subject of this address is the organisation of thought, a topic evidently capable of many diverse modes of treatment. I intend more particularly to give some account of that department of logical science with which some of my own studies have been connected. But I am anxious, if I can succeed in so doing, to handle this account so as to exhibit the relation with certain considerations which underlie general scientific activities.

It is no accident that an age of science has developed into an age of organisation. Organised thought is the basis of organised action. Organisation is the adjustment of diverse elements so that their mutual relations may exhibit some predetermined quality. An epic poem is a triumph of organisation—that is to say, it is a triumph in the unlikely event of it being a good epic poem. It is the successful organisation of multitudinous sounds of words, associations of words, pictorial memories of diverse events and feelings ordinarily occurring in life, combined with a special narrative of great events: the whole so disposed as to excite emotions which, as defined by Milton, are simple, sensuous, and passionate. The number of successful epic poems is commensurate, or, rather, is inversely commensurate, with the obvious difficulty of the task of organisation.

Science is the organisation of thought. But the example of the epic poem warns us that science is not any organisation of thought. It is an organisation of a certain definite type which we will endeavour to determine.

Science is a river with two sources, the practical source and the theoretical source. The practical source is the desire to direct our actions to achieve predetermined ends. For example, the British nation, fighting for justice, turns to science, which teaches it the importance of compounds of nitrogen. The theoretical source is the desire to understand. Now I am going to emphasise the importance of theory in science. But to avoid misconception I most emphatically state that I do not consider one source as in any sense nobler than the other, or intrinsically more interesting.

The importance, even in practice, of the theoretical side of science arises from the fact that action must be immediate, and takes place in circumstances which are excessively complicated. If we wait for the necessities of action before we commence to arrange our ideas, in peace we shall have lost our trade, and in war we shall have lost the battle.

Success in practice depends on theorists who, led by other motives of exploration, have been there before, and by some good chance have hit upon the relevant ideas. By a theorist I do not mean a man who is up in the clouds, but a man whose motive for thought is the desire to formulate correctly the rules according to which events occur. A successful theorist should be excessively interested in immediate events, otherwise he is not at all likely to formulate correctly anything about them. Of course, both sources of science exist in all men.

Now, what is this thought organisation which we call science? The first aspect of modern science which struck thoughtful observers was its inductive character. The nature of induction, its importance, and the rules of inductive logic have been considered by a long series of thinkers, especially English thinkers, Bacon, Herschel, J. S. Mill, Venn, Jevons, and others. I am not going to plunge into an analysis of the process of induction. Induction is the machinery and not the product, and it is the product which I want to consider. When we understand the product we shall be in a stronger position to improve the machinery.

First, there is one point which it is necessary to emphasise. There is a tendency in analysing scientific processes to assume a given assemblage of concepts applying to nature, and to imagine that the discovery of laws of nature consists in selecting by means of inductive logic some one out of a definite set of possible alternative relations which may hold between the things in nature answering to these obvious concepts. In a sense this assumption is fairly correct, especially in regard to the earlier stages of science. Mankind found itself in possession of certain concepts respecting nature—for example, the concept of fairly permanent material bodies—and proceeded to determine laws which related the corresponding precepts in nature. But the formulation of laws changed the concepts, sometimes gently by an added precision, sometimes violently. At first this process was not much noticed, or at least was felt to be a process curbed within narrow bounds, not touching fundamental ideas. At the stage where we now are, the formulation of the concepts can be seen to be as important as the formulation of the empirical laws connecting the events in the universe as thus conceived by us—for example, the concepts of life, of heredity, of a material body, of a molecule, of an atom, of an electron, of energy, of space, of time, of quantity, and of number.

But, for the purposes of science, what is the actual world? Has science to wait for the termination of the metaphysical debate till it can determine its own subject-matter? I suggest that science has a much more homely starting-ground. Its task is the discovery of the relations which exist within that flux of perceptions, sensations, and emotions which forms our experience of life. The panorama yielded by sight, sound, taste, smell, touch, and by more inchoate sensible feelings, is the sole field of its activity. It is in this way that science is the thought organisation of experience. The most obvious aspect of this field of actual experience is its disorderly character. It is for each person a *continuum*, fragmentary, and with elements not clearly differentiated. The comparison of the sensible experiences of diverse people brings its own difficulties. I insist on the radically untidy, ill-adjusted character of the fields of actual experience from which science starts. To grasp this fundamental truth is the first step in wisdom, when constructing a philosophy of science. This fact is concealed by the influence of language, moulded by science, which foists on us exact concepts as though they represented the immediate deliverances of experience. The result is that we imagine that we have immediate experience of a world of perfectly defined objects implicated in perfectly defined events which, as known to us by the direct deliverance of our senses, happen at exact instants of time, in a space formed by exact points, without parts and without magnitude: the neat, trim, tidy, exact world which is the goal of scientific thought.

My contention is that this world is a world of ideas, and that its internal relations are relations between abstract concepts, and that the elucidation of the precise connection between this world and the feelings of actual experience is the fundamental question of scientific philosophy. The question which I am inviting you to consider is this: How does exact thought apply to the fragmentary, vague *continua* of experience? I am not saying that it does not apply; quite the contrary. But I want to know how it applies.

Digitized by Google

The solution I am asking for is not a phrase however brilliant, but a solid branch of science, constructed with slow patience, showing in detail how the correspondence is effected.

The first great steps in the organisation of thought were due exclusively to the practical source of scientific activity, without any admixture of theoretical impulse. Their slow accomplishment was the cause and also the effect of the gradual evolution of moderately rational beings. I mean the formation of the concepts of definite material objects, of the determinate lapse of time, of simultaneity, of recurrence, of definite relative position, and of analogous fundamental ideas, according to which the flux of our experiences is mentally arranged for handy reference: in fact, the whole apparatus of common-sense thought. Consider in your mind some definite chair. The concept of that chair is simply the concept of all the interrelated experiences connected with that chair—namely, of the experiences of the folk who made it, of the folk who sold it, of the folk who have seen it or used it, of the man who is now experiencing a comfortable sense of support, combined with our expectations of an analogous future, terminated finally by a different set of experiences when the chair collapses and becomes fire-wood. The formation of that type of concept was a tremendous job, and zoologists and geologists tell us that it took many tens of millions of years. I can well believe it.

I now emphasise two points. In the first place, science is rooted in what I have just called the whole apparatus of common-sense thought. That is the *datum* from which it starts, and to which it must recur. We may speculate, if it amuses us, of other beings in other planets who have arranged analogous experiences according to an entirely different conceptual code—namely, who have directed their chief attention to different relations between their various experiences. But the task is too complex, too gigantic, to be revised in its main outlines. You may polish up common sense, you may contradict it in detail, you may surprise it. But ultimately your whole task is to satisfy it.

In the second place, neither common sense nor science can proceed with its task of thought organisation without departing in some respect from the strict consideration of what is actual in experience. Think again of the chair. Among the experiences upon which its concept is based I included our expectations of its future history. I should have gone further and included our imagination of all the possible experiences which in ordinary language we should call perceptions of the chair which might have occurred. This is a difficult question, and I do not see my way through it. But at present in the construction of a theory of space and of time there seem insuperable difficulties if we refuse to admit ideal experiences.

This imaginative perception of experiences, which, if they occurred, would be coherent with our actual experiences, seems fundamental in our lives It is neither wholly arbitrary nor yet fully determined. It is a vague background which is only made in part definite by isolated activities of thought. Consider, for example, our thoughts of the unseen flora of Brazil.

Ideal experiences are closely connected with our imaginative reproduction of the actual experiences of other people, and also with our almost inevitable conception of ourselves as receiving our impressions from an external complex reality beyond ourselves. It may but that both science and metaphysics start from the same given groundwork of immediate experience, and in the main proceed in opposite directions on their diverse tasks.

For example, metaphysics inquires how our perceptions of the chair relate us to some true reality. Science gathers up these perceptions into a determinate class, adds to them ideal perceptions of an analogous sort, which in assignable circumstances would be obtained, and this single concept of that set of perceptions is all that science needs; unless indeed you prefer that thought find its origin in some legend of those great twin brethren, the Cock and Bull.

My immediate problem is to inquire into the nature of the texture of science. Science is essentially logical. The nexus between its concepts is a logical nexus, and the grounds for its detailed assertions are logical grounds. King James said, "No bishops, no king." With greater confidence we can say, "No logic, no science." The reason for the instinctive dislike which most men of science feel towards the recognition of this truth is, I think, the barren failure of logical theory during the past three or four centuries. We may trace this failure back to the worship of authority which in some respects increased in the learned world at the time of the Renaissance. Mankind then changed its authority, and this fact temporally acted as an emancipation. But the main fact, and we can find complaints[1] of it at the very commencement of the modern movement, was the establishment of a reverential attitude towards any statement made by a classical author. Scholars became commentators on truths too fragile to bear translation. A science which hesitates to forget its founders is lost. To this hesitation I ascribe the barrenness of logic.

It will be necessary to sketch in broad outline some relevant features of modern logic. . . .

I will now break off the exposition of the function of logic in connection with the science of natural phenomena. I have endeavoured to exhibit it as the organising principle, analysing the derivation of the concepts from the immediate phenomena, examining the structure of the general propositions which are the assumed laws of nature, establishing their relations to each other in respect to reciprocal implications, deducing the phenomena we may expect in given circumstances.

Logic, properly used, does not shackle thought. It gives freedom and, above all, boldness. Illogical thought hesitates to draw conclusions, because it never knows either what it means, or what it assumes, or how far it trusts its own assumptions, or what will be the effect of any modification of assumptions. Also the mind untrained in that part of constructive logic which is relevant to the subject in hand will be ignorant of the sort of conclusions which follow from various sorts of assumptions, and will be correspondingly dull in divining the inductive laws. The fundamental training in this relevant logic is, undoubtedly, to ponder with an active mind over the known facts of the case, directly observed. But where elaborate deductions are possible, this mental activity requires for its full exercise the direct study of the abstract logical relations. This is applied mathematics.

Neither logic without observation, nor observation without logic, can move one step in the formation of science. We may conceive humanity as engaged in an

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

LONDON.—At University College a public lecture—the first of a series of six—will be delivered by Prof. J. A. Fleming on "Long-distance Telegraphy and Telephony," on Wednesday, October 18, at 5.30 p.m. Prof. J. Norman Collie, director of the chemical laboratories, will give a lecture on Tuesday, October 31, at 5.30 p.m., on "The Scientific Work of Sir William Ramsay."

MR. A. L. MACAULAY, a son of Prof. A. MacAulay, has been appointed demonstrator in physics in the University of Melbourne.

THE next election to Beit Memorial Fellowships for Medical Research (of which there will not be more than ten awards) will take place on or before January 1, 1917. Applications must reach the hon. secretary, Beit Memorial Fellowships for Medical Research, 35 Clarges Street, W., on or before October 15.

A SERIES of popular lectures on "The Tropical Countries of the Empire," illustrated by the collections of the Imperial Institute, will be delivered by Miss Edith A. Browne on Wednesdays in October, November, and December, at the Imperial Institute, at 3 o'clock, commencing on Wednesday, October 4. Admission to the series of lectures will be free by ticket, for which application should be made to the director of the Imperial Institute, South Kensington.

IT is announced in the issue of *Science* for September 8 that a recommendation that a fund of more than 600,000*l*. for the treatment of cancerous, nervous, and disabling ailments be given to the University of Pennsylvania Hospital has been made by Dr. W. H. Smith, superintendent of the Johns Hopkins Hospital, Baltimore, who was selected by the trustees of the fund to visit Philadelphia and make a survey of its hospitals and medical work and give his opinion as to where the fortune would work the greatest benefit. The fund is the estate and its increment willed for the purpose by the late Anna J. Jeanes, a noted Friend philanthropist, who died in 1908.

THE governing body of the Northampton Polytechnic Institute, Clerkenwell, E.C., is not this year publishing the usual annual issue of its "Announcements," but will start and carry through during the current session as many of the courses and classes announced for last year as may be justified by the applications for enrolment received at the commencement of the session. It is hoped that day and evening courses will be held in civil, mechanical, and electrical engineering, in technical optics, and in horology. The engineering courses include subsections in automobile work, aeronautics, and radio-telegraphy. In addition there are to be evening courses in electrochemistry, metallurgy, and domestic economy.

THE instruction given in the evening courses in technology in the University of Leeds, a prospectus of which for the current session has been received, are co-ordinated with the city scheme for evening and time-table. Senior day students of the chemistry and dyeing department of the Bradford College may attend without payment of fee certain lecture courses at the University. University students may similarly attend for work in the college practical dye-house and finishing shed. Third-year students of engineering in the college may attend the University engineering laboratory for work on the refrigerator plant, air-compressor, and hydraulic installation without payment; and University students may similarly attend for work in the college power-house.

A MEETING of the Committee for the Management of the British Prisoners of War Book Scheme was held on Friday last at Whitehall, when the following officers were elected:—Chairman, Mr. A. T. Davies (Board of Education); treasurer, Rear-Admiral J. F. Parry, C.B., hydrographer to the Navy. The appointment of a secretary was held over. A gratifying report was read from the principal examiner to the Board of Trade (Marine Department) on the result of the recent examinations held at the camp at Groningen, in Holland. Evidence is also coming to hand from camps as far distant as Asia Minor of considerable development in the organisation of educational work among the men interned there. From these camps a continuous stream of applications for books for serious study was reported to the committee, who expressed the hope that the public will continue, by offers of suitable books (new or second-hand), to support a war charity the need for which was daily becoming more and more evident and the machinery of which was being increasingly taken advantage of by the friends and relatives of prisoners in all parts of the British Empire. Further particulars respecting this war charity and its work can be obtained on application to Mr. A. T. Davies, at the Board of Education, Whitehall, London, S.W. All communications should have the words "Prisoners of War" written in the left-hand corner of the envelope.

SIR CHARLES WAKEFIELD, Lord Mayor of London, announces that the council of the Lord Kitchener National Memorial Fund has resolved to found a number of scholarships which will enable young Britons destined for a commercial career to travel, study, and gain business experience in the countries of the Allied nations—viz. France, Russia, Italy, Japan, Belgium, Rumania, Portugal, and Serbia. The scholarships will be continued from year to year for all time, and will be of the annual value of about 150*l*. each. They will be for the sons of deceased and disabled officers and men of the Navy and Army, and young men from eighteen to twenty-five years of age who have served with the Forces. The intention is that those elected to hold scholarships should begin their studies almost immediately, that they should receive instruction (*a*) in Russian, French, Italian, and other languages; (*b*) in economics; (*c*) in business principles and business methods (in offices or factories as circumstances may determine), and that immediately at the close of the war they should be sent for a year to travel in one or other of the Allied countries and to continue their studies in that country with the view of gaining (*a*) a close familiarity with its language, and (*b*) an

## SOCIETIES AND ACADEMIES.

### PARIS.

**Academy of Sciences,** September 11.—M. Camille Jordan in the chair.—A. **Lacroix**: The constitution of the volcanic rocks of the extreme north of Madagascar and of Nosy bé; the ankaratrites of Madagascar in general. Five complete analyses are given of rocks from the north of Madagascar, four of rocks from the island of Nosy bé, and six of ankaratrites.—E. **Lebon**: A new table of divisors of numbers.—L. **Godeaux**: The involutions belonging to algebraic surfaces.—J. **Guillaume**: Observations of the sun, made at the Lyons Observatory during the first quarter of 1916. The results of observations made on sixty-one days are summarised in three tables, showing the number of spots, their distribution in latitude, and the distribution of the faculæ in latitude.—D. **Eydoux**: The modifications of the phenomena of hammering in pipes of variable thickness and diameter.—P. **Zeeman**: The drift of light waves and solar phenomena.—A. **Perot**: The influence of the wind on the conditions of audibility of sound. Gunfire has been heard at a great distance from the battlefield, with an intermediate zone of silence. It is shown that this phenomenon can be explained by assuming that at a certain altitude either there is no wind, or that it is contrary in direction to the wind near the ground-level.—H. **Pellet**: The total destruction of pentoses in the course of alcoholic fermentation. In an attempt to estimate pentoses in the presence of saccharose, by fermenting the latter with yeast, it was found that some pentoses were fermented. Alternative conditions are given under which this fermentation of pentoses can be rendered either total or reduced to negligible proportions.

### WASHINGTON, D.C.

**National Academy of Sciences** (Proceedings No. 8, vol. ii., August 15).—C. D. **Miller**: The absorption coefficients of soft X-rays. The numerical constants in the relation between the absorption coefficients, the density, and the wave-lengths have been accurately determined. The results also indicate that the relationship holds for very much softer X-rays than those of ordinary penetrating power.—E. F. **Smith**: Further evidence as to the relation between crown gall and cancer. There are discussed: fundamental concepts, human and animal tumours for which no cause has been discovered, earlier discoveries in plants, further discoveries, other resemblances of crown gall to cancer in man and animals, possibility of the existence of carcinomas and of mixed tumours in plants, production of embryonal teratomata, and bearing of these discoveries on the cancer problem.—G. H. **Parker**: Locomotion of sea-anemones. The pedal portion of a sea-anemone, like its tentacles, must contain a neuromuscular mechanism sufficient for the activity of that part of its body.—G. H. **Parker**: The behaviour of sea-anemones. Sea-anemones are animals the momentary conditions of which are dependent upon the combined stimuli of their immediate surroundings rather than forms that are greatly influenced by their past history, and their unity is not of a pronounced type; they are more in the nature of a sum of parts than they are organic units of the type of most of the higher animals.—J. P. **Iddings** and E. W. **Morley**: A contribution to the petrography of Japan. Seventeen detailed chemical analyses are given of Japanese lavas.—J. **Loeb** and J. H. **Northrop**: Is there a temperature coefficient for the duration of life? In three series of experiments on the fruit-fly Drosophila it is found that the duration of life in the cases examined has a temperature coefficient of 2 for 10° C. This is the same as the temperature coefficient for the velocity of many chemical reactions.—E. **Hubble**: Photographic investigations of faint nebulæ. Of the 103 nebulæ examined, 29 are found to be resolvable into stars. The distribution of the nebulæ is discussed.—E. **Hubble**: Photographic investigations of Kapteyn's selected areas. Areas 1 to 139 have been photographed with the 100-inch reflector. The number of stars per square degree is found to increase with the galactic latitude.—H. **Jeffreys**: The effects of disturbances on the longitude and latitude of a station. The effects of a displacement of the pole of the earth's crust relative to the pole of figure are discussed. The displacement is found to be about 0·″2 in a direction 70° W. of Greenwich

lead, the decrease being almost exactly proportional to the decrease in atomic weight in these samples, so that the atomic volume (18·281) is constant.—National Research Council: A preliminary report to the president of the Academy of the Organising Committee (Messrs. E. G. Conklin, S. Flexner, R. A. Millikan, A. A. Noyes, and G. F. Hale, chairman) of the National Research Council, established by the Academy after conference with the President of the United States for the purpose of co-ordinating the research elements of the country in the interest of national security and welfare.

CAPE TOWN.

**Royal Society of South Africa**, August 16.—Dr. L. Péringuey, president, in the chair.—R. E. **Walker**: The granite of the Schapenberg, Somerset West. The granite of the Schapenberg is essentially a grey, biotite-granito-porphyry intrusive in fine-grained, argillaceous grits of the Malmesbury series. It is essentially an apophysis of one or other of the two large granite masses—the Kuils River granite and the Sir Lowry's Pass granite—which occur the one to the west and the other to the east of the Schapenberg; most probably of the latter. Both fine- and medium-grained varieties occur. At certain points along the contact the granite, owing to absorption of material from the invaded formation, is andalusite-bearing. The granite, particularly near its margin, has been subjected to pneumatolytic action, which has caused the formation of a series of altered granites ranging from school granite on one hand to greissen on the other. The greissen is a quartz-mica-tourmaline rock resembling, in most respects, that of Grainsgill, described by Mr. Alfred Harker in the Q.J.C.S.—J. S. v. d. **Lingen**: The radial lines in Röntgen interference patterns. The author briefly discussed the theory of radial lines, and pointed out that on Friedrich's assumption these lines ought to be present in all interference patterns. Experiments were then described, which support the view put forward by von Laue and the author, viz. radial lines are caused by weakening of the lattice of a rigid crystal. The pattern of $Mg(OH)_2$, where the water molecules were driven off, and resublimated iodine, were exhibited, as well as the pattern of sylvine obtained by Friedrich. The pattern of this iodine shows the transition stage from a three-dimensional grating to a two-dimensional grating. MgO from $Mg(OH)_2$ shows the two-dimensional grating only. "Baurite from biotite" shows the two-dimensional grating by treating biotite with acids.—E. J. **Goddard**: Some observations on *Ozobranchus branchiatus*. This paper contains an account of the leech (*Ozobranchus branchiatus*). Some historical interest attaches to the form, inasmuch as it was probably the first Annulate noted from the Australasian region. The specimens were obtained as parasites on the green turtle. The somite is represented in a very primitive condition, and it is of interest to note that the limitation of the genus to Chelonia as parasites is possibly, as in that of Branchellion to Pisces, indicative of an old association, and bearing out the morphological evidence that these forms are archaic and primitive, and ancestral to the Gnathobdellida and Hemobdellida. The paper deals with the constitution

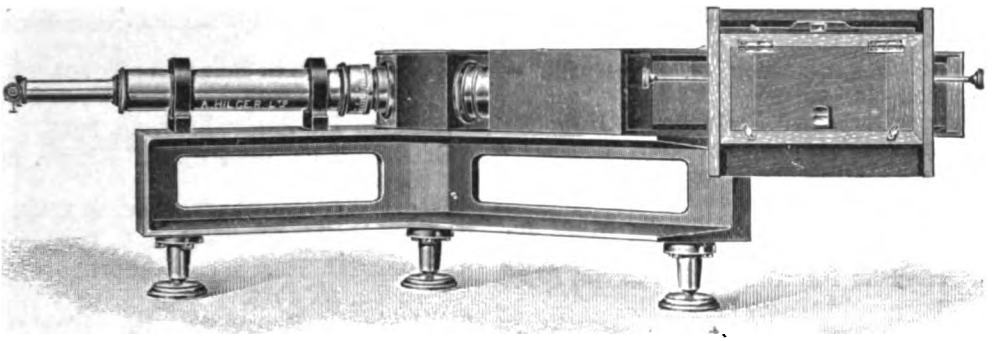
# HILGER QUARTZ SPECTROGRAPHS

**giving the whole spectrum from W.L. 8000 to W.L. 2100 in focus on a flat photographic plate.**



**A wave-length scale** extending over the above mentioned range can be supplied, so adapted that it can be photographed on the plate at the time of taking the photograph of the spectrum, the scale appearing in juxtaposition to the spectrum on development of the plate. The instruments are sent out completely adjusted and ready for photographs to be taken.

**Made in two sizes** { **Size A taking plates** $4\frac{1}{4}'' \times 3\frac{1}{4}''$. „ **C** (see above figure) **taking plates** $10'' \times 4''$.

***Complete description and specimen photographs post free on application to the Makers :***

## ADAM HILGER, Ltd., 75a Camden Road, London, N.W.

**Illustrated Lists of Spectroscopes and Spectroscopic Apparatus of all kinds gratis on request.**

*Telegrams: "Sphericity, Camroad, London."* *Telephone: North 1687.*

## THE BRITISH OXYGEN COMPANY LTD.

**Works** for the production of **Oxygen** and other gases in **London** (Westminster, Greenwich and Stratford), **Birmingham, Cardiff, Wolverhampton, Manchester, Birkenhead, Sheffield, Newcastle-on-Tyne, Glasgow,** and **Sydney, N.S.W.**

**The Company** was formed in 1886 as Brin's Oxygen Company to develop means for the production of Oxygen on an industrial scale.

**The Company** is not only the acknowledged pioneer of the Oxygen Industry, but possesses the largest organisation in the World for the production and distribution of that gas.

**The Company** also manufactures and supplies in cylinders, NITROGEN, HYDROGEN, CARBONIC ACID, and other gases.

**The Company** has developed an extensive engineering business, and has specialised in the design and manufacture of Plant for the production and separation of gases by liquefaction, electrolysis, and other methods.

**The Company** is the exclusive manufacturer in the United Kingdom of apparatus for metal cutting by Oxygen, and also manufactures well-known types of gas Regulators, Oxy-Acetylene and other blowpipes, and a large variety of apparatus for use with gas cylinders.

For illustrated price lists and full particulars application should be made to any of the Company's Works or to the Head Office, **Elverton Street, Westminster, S.W.**

**Microscopes**
(including Petrological and High-Power Binocular),
**Objectives**
(including Apochromatic),
**Microtomes, Optical Lanterns, Photomicrographic Apparatus, etc.**

**WHITE GLASS MICRO. SLIPS.** Thickness 1 to 1·2 mm.

Repairs to Scientific Instruments executed on the premises.

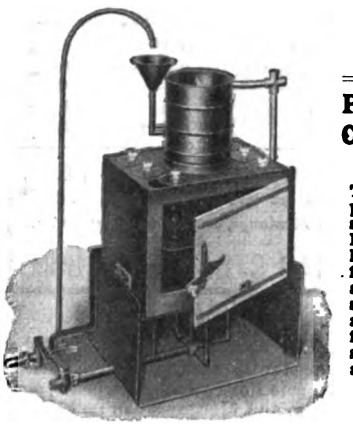
**KORISTKA MICROSCOPES**
OBJECTIVES AND EYEPIECES FROM STOCK.

**OGILVY & Co.**
**18 BLOOMSBURY SQUARE, LONDON, W.C.**
*Telephone: 1674 Gerrard.*

**AUTOCLAVES AND STERILIZERS**

Autoclaves supplied for all purposes in Iron, Steel, or Copper. Tinned or lead-coated, and pressures from ¼ to 100 atmospheres. With or without stirrers. Prices quoted according to capacity and pressure. Made also steam-jacketted, heating by paraffin oil, or oil bath.

We are now coating, with pure lead, electrolytically deposited, the Autoclaves where acid is used.



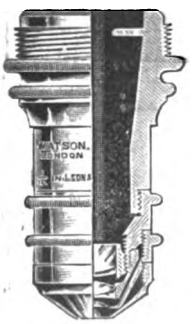
**PATENT [No. 6916] COMBINED OVENS AND STILL.**

This apparatus serves the purposes of drying oven, still, and evaporating bath. Made throughout of best hard rolled copper. Perfectly automatic in action, and economical in gas consumption. Where gas is not available they may be had for heating by steam pressure, petroleum oil, or spirit, and electricity.

*Fully Illustrated Catalogue Free.*

**BROWN & SON,**
ALEMBIC WORKS,
**9 Wedmore Street, Holloway, N.**

**Some Features in**
**WATSON'S "VERSALIC" 1/12 in. OIL IMMERSION OBJECTIVE.**
It has no equal for Laboratory purposes, and is particularly designed for hot climates.



**Mechanical Points.**
- The British Science Guild has recommended that Objectives should be sterilised before screwing home, to prevent growth of fungus, &c., in hot climates. This is done in the "Versalic" ½ in.
- The B.S. Guild also recommended that the mounting should be of a colour to make the Lens easily distinguishable. The "Versalic" ½ in. is finished black.
- In addition, the lenses are NOT set in their Cells with cement, which is apt to become unreliable, but all lenses are fixed with a metal bezel; they cannot th-refore become displaced, the front lens cannot be "pushed in."

**Optical Points.**
- Working distance of exceptional length—the maximum that can be given with maintenance of immersion oil contact. Unusually flat field. Corrected for use on stained objects.
- Magnifying power is that of other ½ in. Lenses to which Laboratory workers are accustomed, viz. ⅛th in. It is a nominal ½ in. Definition is superb, and the Lens a pleasure to use.

The Objective is **British made.** It is designed for the Bacteriologist. It is especially recommended for hot climates. It will stand continuous rough working.

**PRICE £5. IMMEDIATE DELIVERY.**

WATSON'S MICROSCOPES are reliable and accurate. The demand exceeds the supply because their works are necessarily diverted to Optical Munitions. Inquiries are invited, and an approximate date for delivery will always be given.

# MACMILLAN & CO.'S NEW BOOKS.

## Political Frontiers and Boundary Making.

By Col. Sir THOMAS H. HOLDICH, K.C.M.G., K.C.I.E., C.B., D.Sc., Author of "The Gates of India." 8vo. 10*s.* net.

*** Sir Thomas Holdich speaks with the authority of one who has had practical experience in the settlement of boundaries. He gives in this work a complete survey of the questions at issue, and dwells especially on the importance of forming clear ideas of the principles which should govern the adjustment of the new frontiers of Europe at the close of the war.

***1916 ISSUE NOW READY.***

## The Statesman's Year-Book.

Statistical and Historical Annual of the States of the World for the Year 1916. Edited by J. SCOTT KELTIE, LL.D., assisted by M. EPSTEIN, M.A., Ph.D. With Maps. Crown 8vo. 10*s.* 6*d.* net.

## Canada's Future: What She Offers after the War.

A Symposium of Official Opinion. Edited by E. A. VICTOR. Med. 8vo. 6*s.* net.

*THE WESTMINSTER GAZETTE.*—"The book is not only interesting, but so full of facts (and Canadian facts need to be constantly brought up to date, as these are) that it should be in the hands of everyone interested in the Dominion, either as a place of future residence or as one of investment."

## Public Administration in Ancient India.

A Thesis approved by the University of London for the Degree of D.Sc. Econ. By PRAMATHANATH BANERJEA, M.A., D.Sc. Econ., Author of "A Study of Indian Economics." 8vo. 7*s.* 6*d.* net.

## Organic to Human: Psychological and Social.

By HENRY MAUDSLEY, M.D., LL.D., F.R.C.P. 8vo. 12*s.* net.

## Discovery; or, The Spirit and Service of Science.

By Professor R. A. GREGORY. With 8 Plates. Crown 8vo. 5*s.* net.

*THE LANCET.*—"We hope this book will reach a large public. Applied science is playing the predominant part in the war; and when the war is over it is to applied science that the nations will turn in their enormous works of reconstruction, rehabilitation, and repair. This country needs some straight teaching, like that conveyed by Mr. Gregory's book, upon the service that science does, and upon the spirit in which that service is rendered."

PART IV. JUST PUBLISHED.

## A Class-Book of Chemistry.

By G. C. DONINGTON, M.A., late Senior Chemistry Master, City of London School, Author of "Practical Exercises in Chemistry." Illustrated. Crown 8vo. Part I. 1*s.* 6*d.* Parts I. and II. 2*s.* 6*d.* Parts II. and III. 2*s.* 6*d.* Parts I.-III. 3*s.* 6*d.* Part IV. METALS. 2*s.*

## A Manual of Practical Physics.

By H. E. HADLEY, B.Sc., A.R.C.Sc., Principal of the School of Science, Kidderminster. Illustrated. Globe 8vo. 3*s.*

*THE SCHOOLMASTER.*—"The help to be derived from such a text-book is incalculable. To the lonely student it will come as a boon. Its exercises are workmanlike and searching, and its 265 pages are cheap at the price."

## A Text-Book of Practical Physics.

By H. S. ALLEN, M.A., D.Sc., Senior Lecturer in Physics, University of London, King's College, and H. MOORE, A.R.C.Sc., B.Sc., Lecturer in Physics, University of London, King's College. Extra crown 8vo. 8*s.* 6*d.* net. Also PART I. PROPERTIES OF MATTER. 3*s.* net. PARTS II., III., and IV. SOUND, LIGHT, AND HEAT. 3*s.* net. PARTS V. and VI. MAGNETISM AND ELECTRICITY. 3*s.* net.

*THE ELECTRICIAN.*—"To those interested in the elucidation of elementary physical principles the book will be exceedingly useful, and praise is due to the authors for producing so readable a book."

PART II. JUST PUBLISHED.

## Practical Mathematics for Technical Students.

Part II. By T. S. USHERWOOD, B.Sc., Wh.Ex., A.M.I.Mech.E., and C. J. A. TRIMBLE, B.A. Crown 8vo. 7*s.* 6*d.*

*** Previously published: Part I. 3*s.* 6*d.*

*THE TIMES EDUCATIONAL SUPPLEMENT.*—"In this elaborate work the subject is developed and extended for the use of students of engineering and other branches of applied science. . . . The book is lucid and useful."

FEBRUARY—JUNE PAPERS JUST PUBLISHED.

## Mathematical Papers for Admission into the Royal Military Academy and the Royal Military College, February–June, 1916.

THE MANCHESTER MUNICIPAL
SCHOOL OF TECHNOLOGY
(UNIVERSITY OF MANCHESTER).

PRINCIPAL: J. C. M. GARNETT, M.A. (late Fellow of Trinity College, Cambridge).

The Prospectus, forwarded free on application, gives particulars of the courses leading to the Manchester University degrees in the Faculty of Technology, in the following departments:—

MECHANICAL ENGINEERING,
ELECTRICAL ENGINEERING,
SANITARY ENGINEERING (including Municipal Engineering),
THE CHEMICAL INDUSTRIES (including General Chemical Technology, Bleaching, Dyeing, Printing, Papermaking, Brewing, and Metallurgy),
THE TEXTILE INDUSTRIES,
PRINTING AND PHOTOGRAPHIC TECHNOLOGY,
MINING,
ARCHITECTURE.

During the Session 1916-1917, First Year Courses will be specially adapted to the requirements of students who may wish to take Commissions in H.M. Forces.

BATTERSEA POLYTECHNIC, S.W.
Principal—F. H. NEWMAN, M.A., Ph.D.

*Technical Day College* for students wishing to enter the Engineering, Architectural, Chemical, or similar professions.

*University Courses*, day and evening, under recognised teachers, for London University degrees in Science, Engineering, and Music.

*Training Department of Domestic Science* for Teachers of Domestic Subjects.

*Physical Training College* for Teachers of Swedish, Educational, and Remedial Gymnastics.

Departments of *Hygiene and Physiology*, *Commerce*, and *Music*.

*School of Art and Crafts.*

Hostels for Women Students.

For particulars apply to the SECRETARY, Battersea Polytechnic, S.W.

BRADFORD EDUCATION COMMITTEE.
TECHNICAL COLLEGE.
Principal—Prof. W. M. GARDNER, M.Sc., F.I.C.

SPECIAL DAY DIPLOMA COURSES (3 or 4 years) in
(1) Dyeing and Textile Chemistry.
(2) General Industrial and Analytical Chemistry.
(3) Metallurgical Chemistry and Assaying.
(4) Chemical and Gas Engineering.
(5) Research in Textile Chemistry.

*Visits to Works* and the *solution of Works difficulties* are made special features.

DAY SESSION, 1916-17, has now commenced.

A pamphlet—"Industrial Chemistry and Dyeing as a Career for Men and Women"—post free on application.

Education Office, Bradford, October, 1916. BY ORDER.

THE HIGH COMMISSIONER for the UNION OF SOUTH AFRICA invites applications for the CHAIR OF LOGIC AND PSYCHOLOGY at VICTORIA COLLEGE, STELLENBOSCH. Commencing salary £500; passage money; three years' agreement in first instance. Duties to commence middle February, 1917.

Applications, containing information as to age, character, qualifications, experience, health, and religious denomination, must be received not later than November 4, 1916, by the SECRETARY, Office of High Commissioner, Union of South Africa, 32 Victoria Street, S.W., from whom further particulars may be obtained.

BIRKBECK COLLEGE,
BREAMS BUILDINGS, CHANCERY LANE, E.C.

COURSES OF STUDY (Day and Evening) for Degrees of the UNIVERSITY OF LONDON in the
FACULTIES OF SCIENCE & ARTS
(PASS AND HONOURS)
Under RECOGNISED TEACHERS of the University.

SCIENCE.—Chemistry, Physics, Mathematics (Pure and Applied), Botany, Zoology, Geology.

ARTS.—Latin, Greek, English, French, German, Italian, History, Geography, Logic, Economics, Mathematics (Pure and Applied).

# BROWNING'S SPECTROSCOPES

**ALL OF WHICH CAN BE SUPPLIED FROM STOCK.**

## Direct Vision Spectroscopes.

### MINIATURE

These instruments are made with a combination of 3 or 5 prisms and are of considerable dispersion. They will show many of the Fraunhofer lines, the bright lines of the metals and gases, the absorption bands in coloured gases, crystals, or liquids, and any of the leading experiments in Spectrum Analysis. Nos. 103, 106, and 108, being fitted with a Comparison Prism, will show two spectra in the field of view at the same time, so that they may be conveniently compared.

### THREE PRISM MINIATURES.

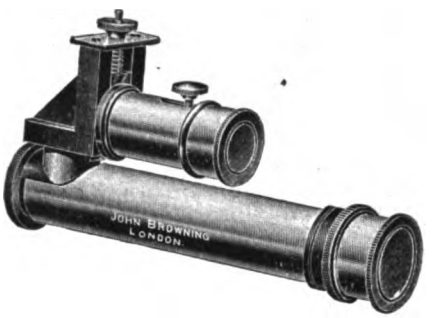
| | | £ | s. | d. |
|---|---|---|---|---|
| No. 101 | With **plain slit** ... ... | 1 | 0 | 0 |
| ,, 102 | ,, **adjustable slit** ... | 1 | 7 | 6 |
| ,, 103 | ,, ,, and **Comparison Prism** ... ... | 1 | 15 | 0 |

### FIVE PRISM MINIATURES.

The following instruments are similar to the above, but are made with a combination of **five Prisms,** giving greater dispersion, and therefore showing the lines and bands more distinctly.

| | | £ | s. | d. |
|---|---|---|---|---|
| No. 104 | With **plain slit,** in Morocco Case | 1 | 5 | 6 |
| ,, 105 | ,, **adjustable slit,** in Case... | 1 | 13 | 0 |
| ,, 106 | ,, ,, and **Comparison Prism,** in Case ... ... | 2 | 0 | 0 |
| ,, 107 | As No. 105, but with **Achromatic Lens,** in Case ... .. | 2 | 0 | 0 |
| ,, 108 | As No. 107, but with **Comparison Prism,** in Case .. ... | 2 | 7 | 6 |

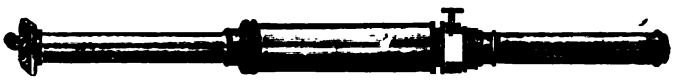
### MINIATURE, WITH MICROMETER.



This instrument is similar to No. 108, but in addition is fitted with *Improved* Photographed Micrometer Scale for gauging the position of the lines and bands of the various spectra.

| | | £ | s. | d. |
|---|---|---|---|---|
| No. 109 | With combination of **five** Prisms, **Adjustable Slit, Achromatic Lens, Comparison Prism,** and **Micrometer Scale,** in Morocco Case ... ... | 8 | 10 | 0 |

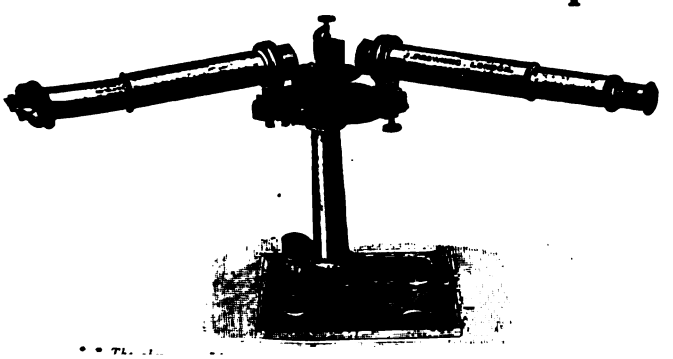
### LARGE HIGH-POWER DIRECT VISION SPECTROSCOPES.



These instruments are the most powerful portable spectroscopes made. They are fitted with a powerful combination of **five large very dense Prisms,** and give as great dispersion as many Table Spectroscopes, widely separating the "D" line in the Solar Spectrum. They are fitted with a movable eye-end by which any line or band of the Spectrum may be brought to the centre of the field of view.

| | | £ | s. | d. |
|---|---|---|---|---|
| No. 110 | In Morocco Case ... ... .. ... ... | 5 | 15 | 0 |
| No. 111 | With **Micrometric Slit,** in Morocco Case ... | 6 | 18 | 6 |
| | Portable Brass Tripod Clip Stand for above ... | 2 | 2 | 0 |

## Chemical Spectroscopes.



### TABLE SPECTROSCOPES AND SPECTROMETERS

These instruments are of the best workmanship throughout; the prisms are of a very dense glass of superior quality, and the object glasses achromatic. The slit is provided with a right-angled reflecting prism, by which two spectra may be seen in the field of view at the same time, and may be easily compared. The lines or bands in any spectrum can be accurately measured in degrees and minutes of angular deviation, and refractive indices can be taken, the arc being divided to 360° and reading by vernier to single minutes.

**Prices from £8 8 0**

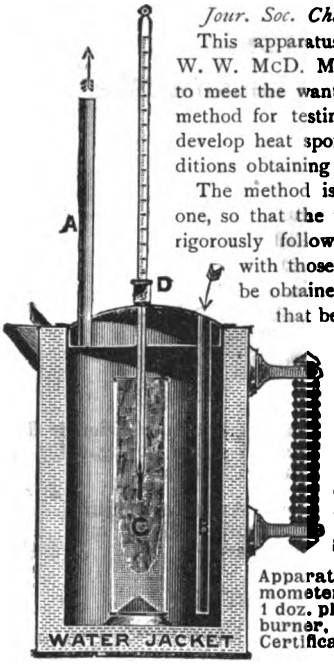
## MACKEY'S CLOTH OIL TESTER.



*Jour. Soc. Chem. Ind.*, 1896 (*p.* 90).

This apparatus has been designed by W. W. McD. MACKEY, F.I.C., of Leeds, to meet the want of an efficient and quick method for testing the liability of Oils to develop heat spontaneously under the conditions obtaining in Cloth Mills.

The method is essentially a comparative one, so that the instructions given must be rigorously followed if results comparable with those of other operators are to be obtained; and it is recommended that before proceeding to the testing of actual examples a few experiments be first made, say, with a good fresh olive oil, as representing a safe oil, and cotton seed oil as representing a dangerous oil, and the results obtained compared with those given in the Tables.

Apparatus complete, with thermometer, 6 wire gauze cylinders, 1 doz. pkts. cotton "wool," stand, burner, and measure. Price with Certificate ... ... **£2 18 6**

(2) *Individuality in Organisms.* By C. M. Child. Pp. x+213. (Chicago: University of Chicago Press; London: Cambridge University Press, 1915.) Price 5*s.* net.

(1) IN this able study of senescence and rejuvenescence Prof. Child gives us the fruits of fifteen years of research on the age-changes of the lower animals. Much of the book is a record of observations and experiments which have not been previously published; the rest is a thoughtful working-out of a new conception of the organism, which must be taken account of by all biologists. The most prominent new feature is the author's attempt to show that "in the organic world in general rejuvenescence is just as fundamental and important a process as senescence." In the higher forms the possibilities of rejuvenescence seem to be very narrowly limited, and may be scarcely recognisable save in connection with sexual reproduction; but in the simpler organisms, such as the Planarian worms on which the author has published many researches, it is a characteristic feature of life.

In seeking to determine the degree of ageing in an organism we are accustomed to look out for certain structural changes familiar in man and mammals, or we measure the decreasing rate of metabolism per unit of substance. For lower animals, however, other tests must be used; thus advantage has been taken of the general relation between metabolic condition and susceptibility or resistance to cyanides or other narcotics. With differences in susceptibility there also correspond differences in carbon dioxide production as estimated by Tashiro's beautifully delicate "biometer." In other cases the susceptibility or resistance of the organism to the depressing agent may be determined indirectly by the creature's ability to become acclimated to a given concentration.

Numerous experiments on Planarians show that the rate of metabolism, measured by the susceptibility method, decreases with advancing age, and it is concluded that a decrease in rate of metabolism is at least very generally associated with growth and differentiation. An isolated fragment of a Planarian begins by developing a new head and tail, and then undergoes an extensive reorganisation into a new individual of small size. Some parts atrophy and disappear; new parts arise and differentiate; the development in reconstitution is not essentially different from embryonic development. All this and much more is familiar, but the novel point is that the reconstituting Planarians are physiologically younger than those from which the pieces came. As measured by the susceptibility method they exhibit rejuvenescence, and "the degree of rejuvenescence is in general proportional to the degree of reorganisation in the process of reconstitution of the piece into a whole" (p. 118).

The next step in the experimental argument is very interesting: it is the demonstration (by the susceptibility method) that pieces spontaneously isolated in Planarians and Hydroids are physiologically younger than the individuals from which they separate. In other words, rejuvenescence is associated with asexual or agamic reproduction. Furthermore, a Planarian starved for months lives on its own resources and becomes reduced in size. Some cells disappear and others become small. This is well known, but the new fact is that the starving animals undergo rejuvenescence, the degree varying with the degree of reduction. If the susceptibility method is trustworthy they become physiologically younger, and this conclusion was corroborated by estimating the production of carbon dioxide. There is here a strong biological argument for asceticism. The starveling is brought back from an advanced age to the beginning of post-embryonic life; it is almost reborn. "The metabolic current is forced to erode its channel instead of depositing material along its course" (p. 179). Moreover, with certain foods a progressive senescence from generation to generation occurs, while with other foods senescence and rejuvenescence seem to balance in each cycle.

In plants and simple animals, such as polyps, asexual reproduction is frequent, and this brings with it some measure of rejuvenescence. "Often the decrease in metabolic rate with advancing senescence is the primary factor in bringing about physiological isolation of parts, reproduction, and rejuvenescence" (p. 260), and thus senescence may be automatically compensated for. Of great interest, also, are various processes of cellular dedifferentiation which occur in both plants and lower animals, and this also will act as a retardation of senescence. In the higher animals the later atrophic stages of senescence are conspicuous, while in the lower forms they either do not appear or else occur in only a few cells at any given time. "The apparent continuity and irregressibility of senescence in man and the higher forms is responsible for the very general belief that the process is irregressible everywhere, but the plants and lower animals show us clearly enough that this is not the case" (p. 289). In the higher reaches senescence is less frequently interrupted, but it is essentially the same throughout, and occurs "wherever the progressive changes are not balanced or overbalanced by regression." With senescence in man and domesticated mammals everyone is familiar, but what of the alleged rejuvenescence? The author answers that some degree of rejuvenescence occurs in certain tissues, but that on the whole it is grievously limited by the greater stability of the substratum. "For his high degree of individuation man pays the penalty of individual death, and the conditions and pro-

Digitized by Google

cesses which lead to death in the end are the conditions and processes which make man what he is" (p. 310).

It might seem that the author's thesis was here petering out, but the next step is important. Prof. Child does not believe much in the "segregation of the germ-plasm"; he thinks that the germ-cells, like the somatic cells, exhibit progressive differentiation and senescence, that "the fully developed gametes are physiologically old, highly differentiated cells, which are rapidly approaching death and in most cases actually do die soon after maturity unless fertilisation occurs" (p. 357). They are of advanced physiological age and low metabolic rate. They must undergo de-differentiation and rejuvenescence before they can enter upon a new period of development. The parthenogenetic egg has not lost its capacity of reacting to isolation, but ordinary gametes can undergo de-differentiation and reconstitution only after fertilisation. In this ingenious way, which cannot be justly represented in brief statement, the author interprets gamete formation as a means of securing rejuvenescence. Reproduction is always the reconstitution of a new organism from a part of one previously existing, but the author stands for the new idea that rejuvenescence occurs during early development, and the zoological evidence that he adduces is very interesting. "The organism, when it begins its active independent life at the end of the embryonic period, is certainly very much younger in every respect than the gametes before fertilisation" (p. 403). It has become younger as it has grown older. This seems a little over-ingenious, but the general idea that the early development means very literally making a fresh start becomes concrete and vivid in the author's exposition.

Let us attempt a more compact statement of the author's interpretation of age-changes. The numerous theories of senescence fall into two groups—those which regard it as an incidental imperfection (due to wear and tear, incomplete elimination of waste products, and so on), and those which regard it as an inevitable feature of development. Prof. Child's experiments point to the second view. After the earliest stages of development there is a progressive change in the direction of greater physiological stability in consequence of changes in the substratum and additions to it in the course of growth and differentiation. As the proportion of relatively stable constituents in the substratum increases, there is a decrease in the metabolic activity of each unit of weight or volume of the organism. Thus cells may become loaded with non-protoplasmic enclosures, and skeletal or supporting tissues arise. It is also probable that the increasing density and aggregation of the colloid substratum may lead to an actual decrease in the rate of chemical reactions, and that the increase in density and thickness and the decrease in the permeability of membranes may retard the exchange through them. Thus and thus does ageing begin while the life is still young. "The decrease in rate of metabolism is a part of development itself, and not an accidental or incidental feature of life. The decrease in metabolic rate during development is in fact a necessary and inevitable consequence of the association of the chemical reactions which constitute metabolism with a colloid substratum produced by the reactions" (p. 184). But there is another side to all this, which has been for the most part overlooked because it is inconspicuous in higher forms. There are processes of reduction as contrasted with growth, of retrogressive as contrasted with progressive development. Accumulated substances and structures may be broken down, and the self-fettered metabolism increases in rate. There is a retrogression towards the embryonic condition, as is familiarly seen in the pupa of a fly. "Dynamically rejuvenescence consists in increase in rate of metabolism, and morphologically in the changes in the substratum which permit increase in rate." And this rejuvenescence is as essential a feature of life as senescence. Ageing has been too much regarded as "a rather mysterious process, quite different from anything else in the life cycle," but it is simply a conspicuous expression of what occurs in minor rhythms continually. Thus the period of "loading" of a gland-cell is a period of decreasing metabolic activity (of "senescence"), and the period of discharge one of increasing activity (of "rejuvenescence"), which makes possible a repetition of the cycle. So there are alternations of fatigue and recovery, of quiescence and activity, and "whether we call one cycle an age-cycle and another something else is of little importance, except as regards convenience." It is further suggested that there may be secular senescence and rejuvenescence in racial evolution. "The age-changes in the organism are merely one aspect of *Werden und Vergehen*, the becoming and passing away, which make up the history of the universe."

It is out of the question to express in a few lines more than an appreciation of a carefully executed piece of work of this magnitude. It is rich in suggestiveness and original ideas, and gives us a new view of the organism and its vital tides. Much depends on the soundness of the susceptibility method of determining the rate of metabolism, for a great deal of the evidence relies on this. We confess to a feeling that the superstructure of interpretation is too broad for the Planarian basis on which it mainly rests. Time is required for consideration of the evidence given of rejuvenescence in the early stages of development in higher animals, and for weighing the author's reasons for rejecting Weismann's conception of the apartness of the germ-plasm. But it is a great satisfaction to meet with such a fine instance of resolute biological thinking, and we offer Prof. Child our congratulations.

(2) The author's main contribution to the problem of organic individuation is the demonstration of a distinct gradient in the rate of metabolic reactions along the chief axis of various axiate types. The apical or head region is primarily the region of highest rate of metabolism, and, in general, regions nearer to it have a higher rate than regions farther away. Moreover, in experiment

Digitized by Google

reproduction, "the apical or head region develops independently of other parts, but controls or dominates their development, and in general any level of the body dominates more posterior or lower levels and is dominated by more anterior or apical levels." The dominance depends primarily upon the rate of metabolism, and seems to operate by impulses, excitations, or changes transmitted in various ways from the dominant region to other parts of the body.

What Prof. Child seeks is a dynamic conception of the organism, and he maintains that "the individual is primarily a metabolic gradient in a specific protoplasm; the only primary difference between the dominant and other levels of the gradient is a difference of metabolic rate. At this time the products of metabolism at different levels of the gradient are not specifically different, but differ in quantity." But the differences in rate at different levels bring about, sooner or later, differences in constitution and character of the protoplasmic substratum. Here one stable substance and there another remains as a constituent of the colloid substratum. Thus "each level of the gradient develops a characteristic protoplasm, and the character of the protoplasm in turn modifies and alters the character of the reactions, and so specific, or what we call qualitative, differences arise, and different specific substances may be produced at different levels of the gradient." Then for the first time chemical or transportative correlation in the commonly accepted sense becomes possible. The individual is there before the orderly specificities of chemical correlation are present or possible. "The starting point in differentiation is in differences in metabolic rate." The organism is a dynamic reaction system—"a protoplasm of specific constitution with a corresponding metabolic specificity." Individuation is a relation of dominance and subordination of parts. Development is a realisation of the capacities or possibilities which are given in the physico-chemical constitution of the fundamental reaction system. We have said enough to indicate the trend of the author's exceedingly interesting theory, which is doubtless a good one to work with, though it seems to our prejudiced vision to leave half of the Prince of Denmark out of the play. For, colloid substratum and metabolic gradient notwithstanding, we must regard even Prof. Child's Planarians as psycho-physical beings, mind-bodies or body-minds as you will, but organisms as well as mechanisms through and through.

## HYDRAULIC FORMULA RECONSTRUCTION.

*Hydraulic Flow Reviewed.* By A. A. Barnes. Pp. xi+158. (London: E. and F. N. Spon, Ltd., 1916.) Price 12*s.* 6*d.* net.

THE book is in two parts, the first of which deals with the flow of [illegible] finding the variation in the coefficients of accepted formulæ unsatisfactory, he was led to review the whole subject of the laws of flow, with the result that he has devised a series of formulæ in which the coefficient is independent of variations in the size or gradient of the conduit. Taking the equations of five well-known experimentalists, which he styles "the more salient formulæ" on the subject, he shows that they are of the form $= Km^{\frac{1}{2}}i^{\frac{1}{2}}$. He then points out that the square root indices of $m$ (the hydraulic mean depth) and of $i$ (sine of slope) are incompatible with a constant value for the coefficient $k$, for a particular class of pipe or channel. In accordance with the precedent set by Hagen and followed by Thrupp and others, he recommends the adoption of the more general expression $v = Km_{\alpha}i^{\beta}$, and from the analysis of a considerable number of published data he is enabled to assign a series of values to $K$, $\alpha$, and $\beta$ which give consistent and satisfactory results when applied to a wide range of cases. The formulæ thus obtained are sixteen in number, of which we only quote the first as typical of the rest. For new asphalted cast-iron pipes the value is $v = 174{\cdot}1m^{\cdot769}i^{\cdot529}$. The results are plotted in diagrammatic form for reference, and the advantages of using a system of logarithmic co-ordinates (which give straight-line diagrams) for this purpose are pointed out.

In the second part of the book, dealing with the measurement of water by means of triangular notches, rectangular weirs, and circular orifices, the author discards the basic expression in common use, and advocates the application of the general formula adopted in part i., which he casts in the form $v = Km^{\alpha}H^{\beta}$. For a right-angled V notch this becomes:—

$$v = 2{\cdot}462m^{-\cdot00703}H^{\cdot48703}$$

whence $Q = 2{\cdot}48H^{2\cdot48}$.

It is interesting to note that this latter expression corresponds very closely with the results obtained quite recently by Messrs. Gourley and Crimp in researches made on the river Alwen. Their formula reads:—

$$Q = 2{\cdot}48nH^{2\cdot47}$$

($n$ is the tangent of half the included angle of the notch, and, therefore, is unity for a notch of 90°).

For weirs with end contractions Mr. Barnes has determined:—

$$v = 3{\cdot}324m^{\cdot11}H^{\cdot38},$$

and for weirs without end contractions:—

$$v = 3{\cdot}324m^{-\cdot02}H^{\cdot51},$$

while for circular orifices:—

$$v = 4{\cdot}652m^{-\cdot015}H^{\cdot5}.$$

There are a large number of authenticated results incorporated in the volume, tabulated in support of these equations, as well as plates giving the results graphically. The author

As a concise and comprehensive *résumé* of the results obtained from a wide range of experimental work, combined with a striking revision of their mathematical expression, the volume is a welcome and valuable addition to the literature on the subject. B. C.

## SERUM REACTIONS AND BACTERIAL THERAPY.

*Applied Immunology: The Practical Application of Sera and Bacterins Prophylactically, Diagnostically, and Therapeutically.* By Prof. B. A. Thomas and Dr. R. H. Ivy. Pp. xv+359. (Philadelphia and London: J. B. Lippincott Co., 1915.) Price 16*s.* net.

THIS book gives an account of those "reactions" employed in the diagnosis of disease which are based upon alterations in the body-fluids resulting from the action of micro-organisms or from the introduction of foreign proteins, and of the treatment of morbid conditions with serums, bacterial vaccines, etc. These reactions and treatment may be classed under the term "immunology," since they are based upon processes which commonly result in the living body in a state of immunity or resistance to the material—micro-organism or protein—which produces them. This material is named the *antigen*, and the substances which are the outcome of its action are known as *anti-bodies*.

The opening chapter of the book deals with the subject of immunity, its kinds and mode of production, and with the history and development of immunology; the second and third chapters give an account of antigens and anti-bodies and of Ehrlich's side-chain theory. These subjects are treated simply and briefly, but fully enough for the object of the book, which the authors state has been "to crystallise and detail the practical phases of serum and bacterin applications in medicine, thereby enabling the student and general practitioner, with even a slight laboratory experience, to appreciate the significance of, and more competently apply the principles underlying, immunology." In chap. iv. anaphylaxis or hypersusceptibility is described, but we miss any reference to Bordet's theory of its mode of production. The preparation and properties of the various antitoxins and anti-sera are then described, together with certain miscellaneous sera and extracts, and their use in treatment. While usually full enough, some sections appear to be too brief; thus, anti-tuberculosis sera are dismissed in four lines, and no mention is made of Spengler's I.K. serum.

The subject of agglutination and its use in diagnosis are next considered. Dilution of the serum by means of a Wright's pipette is described, but no mention is made of the "throttled" pipette which is so convenient for this kind of work, nor is the subject of "zones of no reaction" alluded to—an omission of some moment.

In chaps. x. and xi. the precipitin reaction and its application for the recognition of blood-stains, etc., and lysis or solvent action are described.

The important subject of complement fixation is next dealt with, and the employment of this reaction for the diagnosis of syphilis (the Wassermann reaction) naturally occupies the premier place. Full details are given of the method of carrying out this reaction, but we should have liked fuller information on the meaning of the phenomenon of fixation in the absence of antigen and on the reaction with cerebro-spinal fluid.

Miscellaneous biochemical reactions, including the Abderhalden reaction, have a few pages devoted to them; and the important subjects of the tuberculin and similar reactions and tuberculin therapy are next considered at some length, following on conventional lines.

The subjects of phagocytosis and recovery from bacterial infections are then dealt with, leading up naturally to a consideration of bacterial inoculations, the opsonic index, and vaccine therapy. This section is somewhat slipshod, for the authors have not clearly distinguished between *preventive* and *therapeutic* inoculations. Thus it is stated that "treatment" of bubonic plague with bacterial suspensions has been extensively practised, and that "therapeutic" inoculation greatly reduces the severity of attacks; in both cases *preventive* treatment or inoculation is really meant.

In an appendix the serum treatment of hæmorrhage, organotherapy, and chemotherapy with salvarsan, etc., are briefly but sufficiently considered.

The book is illustrated with a number of figures, charts, and plates, some of the last-named being coloured. We notice an error occurring throughout the chart illustrating the Wassermann reaction, the incubation temperature being stated to be 56° C. instead of 37° C.

The book, while capable of improvement in many directions, may be recommended as giving a useful survey, free from too much detail and technicalities, of the subject of immunology.

R. T. HEWLETT.

## SCHOOL MATHEMATICS.

(1) *Analytic Geometry.* By Prof. H. B. Phillips. Pp. vii+197. (New York: John Wiley and Sons, Inc.; London; Chapman and Hall, Ltd., 1915.) Price 6*s.* 6*d.* net.

(2) *Problems in the Calculus, with Formulas and Suggestions.* By Dr. D. B. Leib. Pp. xi+224. (Boston, Mass., and London: Ginn and Co., 1915.) Price 4*s.* 6*d.*

(3) *Mathematical Tables for Class-room Use.* By M. Merriman. Pp. 67. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1915.) Price 2*s.* 6*d.* net.

(4) *Rural Arithmetic.* By A. G. Ruston. Pp. xi+431. (London: University Tutorial Press, Ltd., 1916.) Price 3*s.* 6*d.*

(1) PROF. H. B. PHILLIPS believes that the differential calculus should be given to the student in college at the earliest possible moment, and that to accomplish this a short course in analytic geometry is essential. He

Digitized by Google

has therefore written this text to supply a course that will equip the student for work in calculus and engineering, without burdening him with a mass of detail useful only to the student of mathematics for its own sake. The result is a very attractive little book. The author has picked out the easy and fruitful bits of his subject without concerning himself greatly whether the topics chosen are conventionally elementary or advanced. He gives us a book very different from the stock "analytical conics," for the conic falls into its place among other curves, and is not studied under a microscope. For example, we have nothing about the equation of the tangent to a conic; presumably the author would take tangents after $dy/dx$. On the other hand, we have sections on periodic functions, empirical equations, parametric representation, co-ordinates in space, surfaces. The book is one that might very well be used with a class of intelligent non-specialists in their last two years at an English public school, at a stage when the function of mathematics is to broaden their outlook. It would serve equally well as an introductory course for a specialist.

The book is full of pleasing practical touches—*e.g.* "But on other problems, *notably in work with alternating currents*, an interpretation can be given to the process of extracting the square root of a negative number, and then such results are entirely real."

(2) Most English text-books on the calculus are fairly well provided with exercises, but anyone who wants more will find a good collection here. The sets on maxima and minima are especially practical. Students of foreign fashions in notation will note the absence of $\sin^{-1}$; arc sin is used instead. The hyperbolic functions have not found admission, which seems a pity. The sets of exercises are prefaced by brief directions and plain warnings; the directions however are, from an educational point of view, too much in the way of rules—*e.g.* "To find $d^2y/dx^2$ (when $x$ and $y$ are given as functions of $t$) use the somewhat cumbersome formula

$$\frac{d^2y}{dx^2}=\left(\frac{dx}{dt}\cdot\frac{d^2y}{dt^2}-\frac{dy}{dt}\cdot\frac{d^2x}{dt^2}\right)\Big/\left(\frac{dx}{dt}\right)^3,$$

etc." (p. 29). On p. 81 the precise meaning of "in general" is not clear in the sentence: "Expansion into series is, in general, useful in calculations only when the series is convergent."

(3) This book contains many more tables than are commonly used in British class-rooms—*e.g.* cubes and cube roots, tables of $n^{\frac{1}{2}}$, $n^5$, $n^{\frac{1}{4}}$, $n^{\frac{1}{3}}$, $n^{\frac{2}{3}}$, areas and circumferences of circles, volumes of spheres, circular segments, chords, etc., together with five pages of weights and measures (from which it appears that the American yard differs from the British yard, being defined as 3600/3937 metres). On the other hand, there is no full table of secs and cosecs. Sine and cosine share a table, as do tan and cot. The "arguments" are given to three significant figures, or for every ten minutes in the trigonometrical tables. There are no difference columns, and to obtain a fourth significant figure, or the intermediate degrees, it is necessary to interpolate. Some of the functions are given to four significant figures, some to five; the principle underlying the choice of four or five is not mentioned. The author has broken with the curious tradition (the origin of which we should like to know) that ten should be added to the log of a circular function.

For British schools this book will probably be considered to contain too much in one way and too little in another (*e.g.* difference columns). The type is too small for young eyes.

(4) This book contains chapters on household accounts, commercial arithmetic, business letters, soils, manures, crops, live-stock, foodstuffs, dairying, mensuration, levelling, brickwork and building construction, water supply, work and power, measurement in the field. The explanations of arithmetical processes are undistinguished and sometimes old-fashioned (*e.g.* inverting the multiplier in contracted multiplication). But we imagine that this is not the part of the book in which the author is most interested. The description of all practical matters concerning farms and farmers is well written, and the numerous examples have a most realistic and practical appearance. How much more interesting it must be to find the volume of a "mangel pie" than of a mere prism! C. G.

## OUR BOOKSHELF.

*Aids to Bacteriology.* By C. G. Moor and William Partridge. Third edition. Pp. viii+278. (London: Baillière, Tindall and Cox, 1916.) Price 3*s.* 6*d.* net.

THIS well-known little book, now in its third edition, contains an extraordinary amount of information within a small compass, though necessarily in a condensed form; in fact, the whole range of subjects included under the term "Bacteriology" is covered by it. Migula's classification of the Bacteria now replaces that of Heuppe, and as regards bacterial mutability, the authors remark that this is largely of academic interest, and that in practice species tend to crop up fairly true to type. Antibodies, apparatus, culture media and methods of examination are surveyed, and all the principal pathogenic bacteria and protozoa are described. In addition, the moulds, yeasts, fermentation, and enzymes are dealt with as well as the bacteriology of water, milk and other foods, air, soil and sewage, and disinfection and disinfectants; little seems to have been missed and few errors occur. It is a pity that *B. perfringens* as a synonym for *B. Welchii* is not mentioned, for it is so commonly used now. Agricultural bacteriology has two or three pages devoted to it, including nitrogen fixation, nitrification and sterilisation of soil. The filterable viruses are dealt with, and some recent work on the meningococcus and other topics is referred to in a brief appendix. Altogether we may congratulate the authors upon having compiled an exceedingly comprehensive and useful little book.

Digitized by Google

*Mind and Health Series. The Influence of Joy.* By George Van Ness Dearborn. Pp. xviii + 223. (London: William Heinemann, 1916.) Price 5*s.* net.

PROF. PAVLOV of Petrograd has shown in famous experiments that digestion is affected favourably or unfavourably by emotional conditions, and his work has been followed by Cannon, Carlson, Crile, and others. The author of this volume has studied the influence of joy on blood pressure, and has devoted some attention to the psycho-biology of the emotions. His thesis is that joy is an important factor in the health of the body, and his illustrations refer to the influence of joy (1) in stimulating secretion, the movements of the food canal, and the process of absorption; (2) on the circulation; and (3) on the general integrative function of the nervous system.

The evidence given as to the influence of joy on secretion and blood pressure is more convincing than that under the third head. Much attention is given to the influence of emotion on the secretion of adrenalin and all that follows even a slight increase in the amount of that powerful substance.

The author writes with enthusiasm and occasionally with exuberance, but it is with good science that he confirms the good sense of the cheerful-minded in all ages, who have realised that "a merry heart is the life of the flesh." There is much salutary counsel in what Prof. Dearborn has to say regarding the cultivation of the will to be glad, and he has made a very useful contribution to psycho-biology.

*Manual of Russian Commercial Correspondence.* By Mark Sieff. Pp. xx + 232. (London: Kegan Paul, Trench and Co., Ltd., 1916.) Price 3*s.* 6*d.* net.

THIS is a welcome addition to the student's library. Admirably qualified for the task, the author has compiled a veritable *multum in parvo*, and the student who masters its contents will have little to apprehend when called upon to deal with Russian correspondence. A valuable feature is the section, modelled on the plan adopted by N. A. Blatov in his "Manual of Russian Commercial Correspondence," setting forth with admirable clearness the general plan on which letters on various subjects should be constructed. It constitutes a lesson in orderly arrangement and concise statement which might be profitably studied by correspondents in any language. Where so much is excellent it seems almost hypercritical to point out that the English phraseology is in places somewhat cumbersome and might with advantage be simplified, and also that here and there the English idiom is not quite correct. But these are minor blemishes which in no way detract from the utility of the work. As it is one thing to read print and a very different matter to decipher handwriting, we would suggest that it might be of assistance to students if a future edition contained a few facsimile specimens of actual Russian letters.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### Optical Deterioration of the Atmosphere in July and August, 1916.

DR. MAURER, director of the Swiss Federal Meteorological Institute, has forwarded to me a note on the optical deterioration of the atmosphere noticed in the Alps in the summer which has just passed. At his request I enclose a translation of his note, as the subject is likely to interest your readers.

NAPIER SHAW.

Meteorological Office, South Kensington, London, S.W., September 21.

Remarkable optical deterioration of the atmosphere became apparent in the Swiss Alps during the last ten days of July by the persistently abnormal magnitude and unusual intensity of the bright patch round the sun, to which the name aureole is sometimes assigned. Observations in previous years have established a well-defined minimum during the summer months, both in the diameter and the intensity of the solar aureole, but during the present year, from July 23 until the middle of August, the diameter generally attained 120° to 130°, and on August 25 even 140°, with relatively great intensity. Abnormal extension of the aureole was also observed after July 21 at high levels on the Alps, above 3000 metres, and a true brown Bishop's-ring was seen on August 3–4 on the high peaks of the Upper Engadine.

On August 6 twilight phenomena were very abnormal. The "purple light" was entirely absent; the westerly earth-shadow was very indefinite, and the eastern twilight-arch of the zodiacal light was similarly affected. The western sky, at first of a homogeneous pale yellow colour, showed a peculiar cirrus-like structure for some time after sunset. At first the stratification was strictly horizontal, but later on it appeared undulating, or in flaky form. It did not disappear until darkness set in. Similar phenomena were observed in 1883–4, 1902–3, and 1912, in connection with the much-discussed optical deterioration of the atmosphere in these years. After the end of July this remarkable cirrus-like layer could be seen best in the higher Alpine regions, but a bright "purple light" was not seen there either in July or August. The cause of the deterioration is for the time being still in doubt. Up to the present no reports of volcanic eruptions have come to hand from any part of the globe.

Zürich, September.

### Science in Education.

IN reply to "F.R.S.; F.B.A." (NATURE, September 28, p. 69), may I express the hope that, whatever may be the custom in France, those who discuss the place of science in education, when they say science will mean science, and not "Egyptology, classical archæology, history, art, linguistics, Indics, Sinics, Hellenics, philology (Latin and Celtic), French language and literature, Italian, Spanish, English, German, law, and economics"? No one wants to deny that the study of man holds as large a place as the study of Nature. Man has never yet tired of studying himself, and needs little encouragement to continue doing so. But the progress of the modern world is due to the fact that an increasing number of minds have escaped the vicious circle of these introspective examinations and begun to study the realities of external Nature.

Mr. Carnegie in 1901 gave a million pounds to provide funds "for improving and extending the opportunities for scientific study and research in the Universities of Scotland, my native land," to quote from his trust deed. In the University of Aberdeen, of which I have the honour to be a member, out of 132,000*l.* allocated from this benefaction in the period of 15¾ years, a bare one-quarter has gone to science; 52,118*l.* has gone to endow one professorship in history and five lectureships in French, political economy, German, education, and constitutional law and history; 24,750*l.* has been assigned to provide new buildings for teaching arts subjects, a new examination hall, and an extension of the library; 26,750*l.* has gone, 15,750*l.* to maintenance of the library and 11,000*l.* for provisional assistance in teaching, science being represented in this to an indefinite extent. The remaining 28,382*l.* has gone to science, 15,750*l.* for the equipment of laboratories, and 12,632*l.* as an endowment for a lectureship in geology. With reference to the latter, the Geological Department, taking the figures for the year before the war, was entirely supported by the fees paid by the students, and geology got the interest of the 12,632*l.* in the same sense as the Postmaster-General gets the sovereign when you purchase a 20*s.* postal order. Personally I think calling science what is not science needs to be watched and checkmated.

FREDERICK SODDY.

University of Aberdeen, September 30.

## AN IMPERIAL DEPARTMENT OF MINERAL PRODUCTION.

THE presidents of the technical institutes most closely connected with the production and utilisation of our mineral resources have addressed to the Advisory Council for Scientific Research a memorandum advocating the establishment of a central Government Department, the duty of which should be to foster the development of the mineral resources of the British Empire. Whatever form such a department may take, the need for its creation is very obvious. In Great Britain no such department exists. The Geological Survey, under the Board of Education, records the existence of mineral deposits, but always from the point of view of the geologist, whose main interest lies in their mode of occurrence and not in their exploitation. The Inspectorate of Mines under the Home Office is concerned only with the due policing of mines from the point of view of safety; its ideal would be a state of affairs in which mining accidents were reduced to zero; and even though this were brought about by the cessation of all mining, the Inspectorate of Mines would have fulfilled the object for which it exists. The Board of Trade, the Imperial Institute, and many other departments of the Government take a more or less desultory interest in mineral production, but there is no one department the special duty of which it is to watch over the development and proper utilisation of our mineral resources.

What is needed is a Ministry of Production, or something equivalent thereto, which should have for its particular object the care of developing all the natural resources of the Empire. All natural products may be divided into three groups: they are produced by the cultivator, by the hunter or fisherman, or by the miner. Of all these the last-named needs the most careful attention, because minerals alone constitute a wasting asset; unlike the other products, they are not renewed, and, once exhausted, are gone for ever. The cultivation of a field on wrong principles will entail losses for a year or two, but these are quite remediable, and the application of proper methods will restore it to fruitfulness; but a mine worked on wrong principles is ruined for ever, and mineral not properly wrought is in the vast majority of cases lost irrecoverably.

It is this consideration that renders the need for a Ministry or Department devoted to the administration of our mineral resources so very urgent. In most Continental countries the minerals have remained the property of the State, and the State has therefore a direct pecuniary interest in seeing to their development as an integral part of the national revenue. In this country and in America the State has found it advantageous to relinquish the State ownership of minerals, it being held that the development of the national mineral resources is thus facilitated, and that such free development is of more benefit to the nation than the revenue which might be derived from its mineral concessions. As regards purely fiscal reasons, these two nations are accordingly not directly concerned in the development of their mineral wealth, but it by no means follows that they should treat the subject with indifference. In the United States there is a Department of Mines that takes a very active interest in encouraging the mineral output. In Canada there is a Department of Mines upon somewhat similar lines, which is doing excellent work, and under the fostering care of which the mineral output of Canada is making rapid advances.

There was a time when Great Britain stood at the head of all nations as a mineral producer, at any rate as regards a considerable number of important minerals and metals; that we have fallen far behind to-day is due no doubt in great measure to natural causes, but their effect has been and is being accelerated by the fact that it has been nobody's business to see to it that our mineral resources were worked to best advantage; whenever legislation has touched mining, it has been to hinder, not to help, mining operations, mainly because there was no great Department of State to look after our mineral interests. Wastefulness in the production and utilisation of our mineral resources has gone on and is going on unheeded and unchecked, mainly again for the same reason. The need for a State Department administered on sound economic lines, as free from political bias as our national methods admit of, is perhaps more urgent for the British Isles in the first instance, but together with this and above this, there should be an organisation for protecting the mineral industries of our whole world-wide Empire, for consolidating the resources of the Empire, and for rendering it impossible that in the future the control of any portion of the Empire's mineral production should ever pass into alien hands.

HENRY LOUIS.

## THE SURVEY LINK CONNECTING THE TRIANGULATIONS OF INDIA AND RUSSIA.[1]

AT the meeting of the International Geodetic Association held in London in 1909 the way was cleared for the completion of a connecting link between Indian and Russian triangulations which would carry scientific measurement from Cape Comorin to Petrograd. This necessitated the extension of a geodetic series across some of the highest and most unapproachable of the snow-capped ranges in the northern Himalayan system. Between Gilgit and Salisbury Peak on the Nicolas (Russian spelling) range of the Pamirs there intervene about 100 miles of inconceivably wild and rugged mountain country distinguished

FIG. 1.—On the Russian East Station of Sarblock, 17,284 ft. From "Records of the Survey of India."

by groups of peaks running to altitudes of more than 20,000 ft. and seamed with a most amazing series of waterways containing the biggest glaciers in the world. Salisbury Peak, near the western end of the Pamir boundary between Russia and Afghanistan, looks southwards across the valley of the river Ab-i-Panja (flowing westward to the Oxus and skirting the southern foot of the Nicolas range) on to the great ridge of the Hindu Kush. From the Hindu Kush southward to the Gilgit river flow three great mountain streams, which afford the only possible approaches northward, *i.e.* the Yasin, the Ashkuman, and the Hunza.

1 "Records of the Survey of India." Vol. vi., "Completion of the Link connecting the Triangulations of India and Russia, 1913." Prepared under the direction of Sir S. G. Burrard. (Dehra Dun, 1914.) Price 4 rupees or 6s.

Setting aside, for the present at any rate, any consideration of making this geodetic connection through Afghanistan or Persia (which, for political reasons chiefly, is out of the question), the choice of an approach to the Russian boundary in the Pamirs lay between these three most difficult routes. The line of the Hunza was eventually selected as leading more directly to a point on the Russian border close to the Chinese frontier, and involving no question of crossing the valley of the Ab-i-Panja, which, lying low between the Nicolas range and the Hindu Kush, is a narrow strip of Afghan territory. Between 1909 and 1911 a series of principal triangulation had been carried

FIG. 2.—A log bridge over the Chapursān. From "Records of the Survey of India."

from Rawal Pindi to Gilgit, thus furnishing a first-class base from which to take off for this northern extension. At the other end of the line two trigonometrical stations had been fixed by the Russian surveyors at the eastern end of the Little Pamir, not far from the Beyik Pass, which offered the necessary points for final connection.

The report under review deals with the efforts of the Indian Survey officers to bridge this gap and reach commanding observation points in the barren and rugged *entourage* of the Hunza Valley, by means of which a geodetic series could be carried successfully to the Hindu Kush. Probably no scientific surveyors in the world have ever

Digitized by Google

been faced with quite such a problem. The difficulties were not merely those of mountaineering and excessive altitude or of narrow valleys flanked by gigantic mountain walls. These regions are subject, *inter alia*, to storms of great violence and suddenness, and it was during one such storm that the camp of a native assistant was struck and his whole party practically put out of action. The roads, or mountain tracks, which lead to the passes of the Hindu Kush have often been described by travellers, and there is no indication in this report that they have improved of late years. Certainly no very great trouble was caused by the nature of the transport requisitioned. All sorts and conditions of men were impressed into service. The regular native staff of the Survey Department and the trained Gurkha assistants drawn from the frontier regiments were all trustworthy under any conditions of stress and difficulty, whilst the coolie carriers, who were chiefly recruited from the Baltis, were quite satisfactory. Lieut. Mason's appreciation of their services is pleasant reading, and speaks well for his tact and consideration in dealing with natives.

It was, on the whole, the technical difficulty of selecting sites for stations of observation, and the incessant demand for strenuous exertion in climbing mountains which possess absolutely no attraction beyond that of the grandest and most savage scenery in the world, which hindered the progress of the party; and it was the successful facing of these difficulties which rendered the completion of this series such a brilliant achievement among the great records of Indian triangulation.

The work in the Pamir highlands was laid out by Lieut. Bell, R.E., whose sudden death ere the work was completed was deeply felt by the whole party. The linking up of two magnificent systems of triangulation, such as those of India and Russia, which would give a continuous and unbroken geodetic system of earth measurement through sixty degrees of latitude, has ever been a most fascinating objective to the scientific geodesist in India, Russia, and England; but whether a narrow series such as this, with uneven sides and angles as factors in the successive figures, will fully satisfy the requirements of geodesy may be questionable. Some of the sides of the figures are very short, restricted by narrowness of the Hunza Valley, and the angles are far from fulfilling the condition of equality in arc. It is, therefore, not claimed for it by the Surveyor-General of India that it represents anything more than a "secondary" series, and it still remains for geodesists to say how far it has succeeded in fulfilling the high scientific requirements that were anticipated from its completion. Incidentally, however, it has been of the greatest practical use, for it has confirmed the values determined by the measurements of the Pamir Boundary Commission in 1895, and proved that the process then adopted of interpolation from distant and definite peaks (which were already fixed by the Indian triangulation on the Gilgit frontier), supported by a constant repetition of observed azimuths, was accurate to a degree which seems to have been unexpected by the present Survey Staff in India, although the coincidence in final values causes no

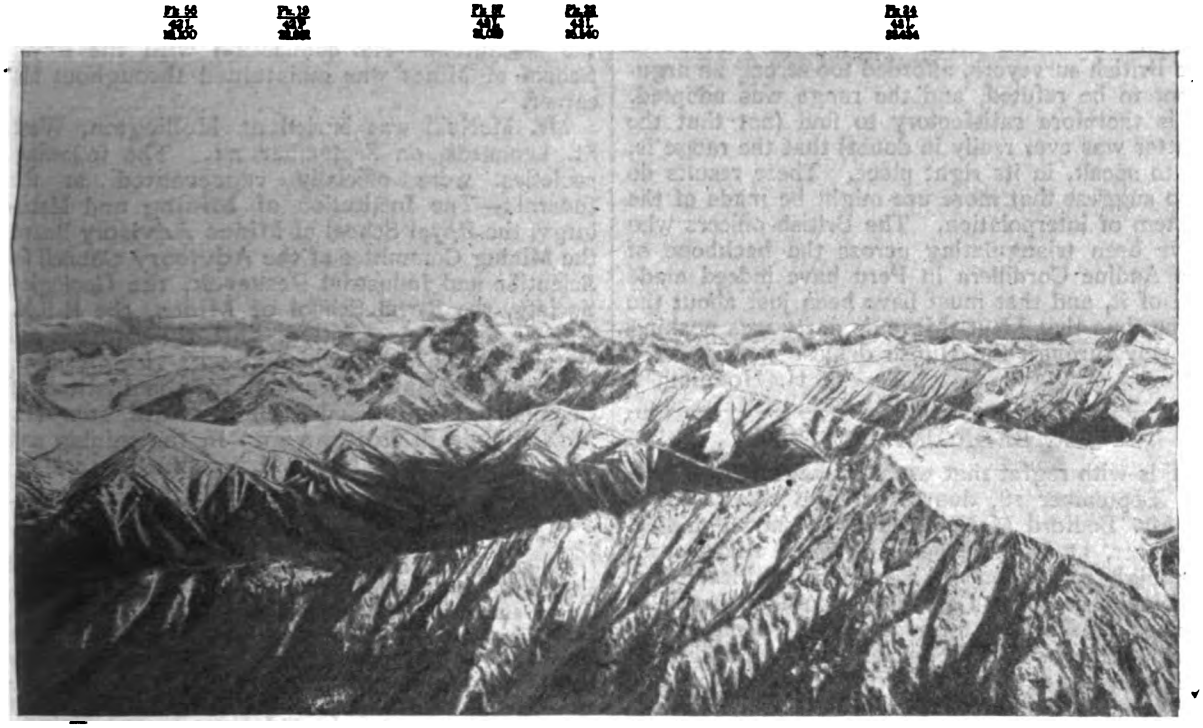

FIG. 3.—The distant Karakoram Range from Tomtek, h.s. 18,608 ft From "Records of the Survey of India."

Digitized by Google

surprise to those who were concerned in that Commission work. Roughly, it may be said that the Commission values obtained in the course of a month or two by the method referred to are in excess of those now fixed by about two seconds of arc both in latitude and in longitude, a displacement which has no effect whatever on the validity of that international boundary which was then demarcated.

This is not unimportant, for it need be no longer a political secret that the adoption of the crest of the Nicolas range as the boundary in question depended on the fact that no part of it was north of the latitude of Lake Victoria. The Russians, by astronomical deduction, maintained that it did in fact bulge over that parallel, but the results of the Pamir triangulation, based on those mighty peaks which were visible from certain high altitudes overlooking the Hindu Kush, combined with astronomical determinations for latitude of the British surveyors, afforded too strong an argument to be refuted, and the range was adopted. It is therefore satisfactory to find (not that the matter was ever really in doubt) that the range is, so to speak, in its right place. These results do also suggest that more use might be made of the system of interpolation. The British officers who have been triangulating across the backbone of the Andine Cordillera in Peru have indeed made use of it, and that must have been just about the same time that Lieut. Mason's party was pushing its way through the Hunza defiles.

T. H. HOLDICH.

## MR. BEDFORD MCNEILL.

IT is with regret that we announce the death on September 18, due to cerebral hæmorrhage, of Mr. Bedford McNeill, the well-known mining engineer, at fifty-five years of age. Apart from his high reputation as a mining engineer, Mr. McNeill's name was almost a household word in connection with the telegraphic code compiled by him, which was issued originally in 1893, and in an enlarged and revised form in 1908. This code is employed almost without exception by mining companies and engineers, to whose use it was specially dedicated, and other business men have found it extremely practical for cable communications.

As a mining engineer Mr. McNeill graduated at the Royal School of Mines in 1880, when the school was still in Jermyn Street; and his professional career as consulting engineer, which began in the office of the late Mr. John Darlington, took him into many parts of the world. He was a member of many learned societies, including the Institute of Chemistry, the Geological Society, of which he was also a Member of Council and Treasurer for some years, and the Iron and Steel Institute. In 1895 Mr. McNeill was elected a member of the Institution of Mining and Metallurgy, of which he soon afterwards became vice-president, and he occupied the presidential chair in 1913–14. His inaugural address in that capacity dealt with the present and future problems confronting the mining profession, particularly as regards the speculative nature of mining and its close association with capital. He pointed out that mining was likely to become more speculative in its character in the future, since, though there were still large areas not yet properly prospected, the engineer may ultimately be driven to working that class of mineral occurrence which presents no visible evidence whatever at surface, and the location and working of which will inevitably demand higher technical skill and involve greater risk of loss of capital than those deposits at present dealt with. During Mr. McNeill's term of office the Institution of Mining and Metallurgy acquired its freehold house at No. 1 Finsbury Circus, which was formally opened on January 13, 1914, by the Lord Mayor of London, and during his presidency also the first steps were taken for securing the Royal Charter which has since been granted to the institution. His connection with the Royal School of Mines was maintained throughout his career.

Mr. McNeill was buried at Hollington, West St. Leonards, on September 21. The following societies were officially represented at the funeral:—The Institution of Mining and Metallurgy, the Royal School of Mines Advisory Board, the Mining Committee of the Advisory Council for Scientific and Industrial Research, the Geological Society, the Royal School of Mines, the R.S.M. Old Students' Association, and the Mining and Metallurgical Club, of which he was vice-president, while floral tributes were sent by the Institute of Chemistry, the Iron and Steel Institute, etc. Mr. McNeill's death creates a gap in the mining and kindred professions that will be difficult to fill.

## NOTES.

AN account of a new means of delineating internal organs *in vivo*, and the localisation of injuries to them, by an electrical method devised by James Shearer, M.D. (Washington, D.C.), at present a sergeant in the R.A.M.C., is given in the *British Medical Journal* for September 30. It is difficult to realise from the description the exact nature of the electrical installation used, but the principle is said to be to impose upon two alternating electric fields of equal strength at right angles the effect of a third field having its origin in the organ under examination. The patient lies on an insulated table, and near him are placed two screens of perforated zinc plate, one horizontal and the other vertical, connected to two separate batteries. A sheet of waxed paper is then put upon a cylinder which is set in rapid rotation, and a needle scribes upon this paper a tracing of the organ under examination, showing at the same time any lesions in it. Prints can afterwards be taken from the record by contact printing with photographic paper. Five illustrations are given in the *British Medical Journal* showing respectively pictures of the brain, kidney, cæcum and appendix, intestine, and liver of injured patients submitted to the process. The brain picture is as clear a delineation of the blood-vessels as is given in text-books of anatomy, but how it could possibly have been produced by a tapping needle upon a rapidly revolving cylinder cannot readily be conceived. Without further details to enable electro-physiologists to repeat Sergeant Shearer's work it is

Digitized by Google

impossible to say more than that the results, if confirmed, represent a very remarkable discovery, which may be of immense advantage in delineating the soft internal structures of the body. So many inventions at first received with incredulity have turned out to be truly useful that we hesitate to speak of this present one as incredible. But with the imperfect details and explanation which are as yet forthcoming, we may be excused if we adopt the attitude of scientific expectancy. We trust it will not be long before the new method is examined by proper experts, and its scientific soundness properly investigated.

AT 3 a.m. (Summer Time) on Sunday last, October 1, Greenwich Time again became the standard time of Great Britain. By an order issued by the Home Office, "the hour 2–3 a.m. Summer Time" was followed by "the hour 2–3 a.m. Greenwich Time." All railway clocks and clocks in post offices and Government establishments were put back one hour, and the Government requested the public to put back the time of all clocks and watches by one hour during the night of Saturday-Sunday, September 30-October 1. From October 1 onwards Greenwich Time will be used for all purposes instead of being limited to the needs of navigation, astronomy, and meteorology, as it has been since May 21. It is announced that the Home Secretary, while satisfied with the results of the Summer Time Act, has appointed a committee to consider the question in all its aspects. A Daylight Saving Bill will probably be reintroduced next year, but Mr. Samuel thinks that certain objections, coming chiefly from northern manufacturing districts, and a number of suggestions and recommendations should be inquired into first. The late experience has shown that the State need not hesitate to introduce any changes which are believed to be for the good of the community. In NATURE of September 28 a correspondent suggested certain modifications of the customary use of a.m. and p.m., so as to avoid the designation of half an hour after midday by 12.30 p.m., while 11.30 p.m. occurs eleven hours later. Mr. C. T. Whitmell writes to say that he made the same suggestion in the *Yorkshire Post* of August 4, and remarks that "some definite agreement as to the way of representing the times between noon and 1 p.m. and between midnight and 1 a.m. is certainly desirable." The Home Secretary's committee might consider this matter, and also the question of designating hours from 0 to 24, so as to avoid the use of a.m. and p.m. altogether.

MR. BENJAMIN KIDD, the author of important books and articles in which a system of social philosophy is developed from an original point of view, died on October 2, at fifty-eight years of age. His first work, "Social Evolution," is the best known, and when it was published in 1894 its originality and force were recognised immediately. The keynote of the work was the declaration that religion is not the enemy of science and enlightenment, but, on the contrary, through the ethical principles of its teaching, has been one of the most important agencies in social development, and is closely bound up with that portion of our nature to which all modern social advance is due, and by which the course of future progress will be decided. Mr. Kidd thus found the causes of the evolution of society and of modern civilisation, not in the growth of intellect and of science, but in the efficiency," when "society, with all its interests in the present, is subordinated to its own future," was regarded as the secret of success and of progress, and its absence was the cause of stagnation. Mr. Kidd was also the author of other notable works. To the tenth edition of the "Encyclopædia Britannica" he contributed a prefatory article on "The Application of the Doctrine of Evolution to Sociological Theory," and for the eleventh edition he wrote the article on sociology. In 1908 he delivered the Herbert Spencer lecture at Oxford upon the subject of "Individualism and After."

A SKIEN newspaper announces the discovery in Telemark, Norway, of a rich mineral field covering several kilometres. Bismuth and silver have been found there, and it is said that there are traces of gold.

THE Faraday Society will hold a general discussion on "Refractories" at its first autumn meeting, the date of which is provisionally fixed for Wednesday, November 8. The discussion will be presided over by Sir Robert Hadfield, president of the society, and the opening paper will be read by Dr. J. W. Mellor.

A LECTURE on "Stresses in Transparent Materials as Revealed by Polarised Light" will be delivered by Prof. E. G. Coker before the Optical Society on Thursday next, October 12, at the rooms of the Chemical Society, Burlington House, Piccadilly, W.

ACCORDING to the *Times* a "meteorite (commonly known as a 'thunderbolt')" fell at Dinas Powis, near Cardiff, on the night of September 26–27, and did some damage. The cause of the damage was, however, not a meteorite, but a lightning-flash. There had been thunderstorms on or about the same day of the month in the previous May, June, and July, whilst it was on March 27 that the famous storm occurred.

MR. LLOYD GEORGE'S allusion to the absence of the nightingale from Wales has caused a long and sharp discussion in the local Press. It is authoritatively stated that during the last thirty years the nightingale has been steadily moving westward in the Principality. In East Glamorgan it is a regular visitor, but has also been reported from Carmarthen, and was heard as far west as Aberystwyth in 1911.

A WIRELESS station has been established on Dickson Island, at the mouth of the Yenisei, by an expedition under the leadership of Dr. Kuchakov, for the purpose of sending meteorological telegrams to the physical observatory in Petrograd. The value of these telegrams will be felt chiefly in Siberia.

DURING the past summer a party of forty men, including five engineers, has been working the large coalfield on Bear Island, between Spitsbergen and Norway. The field has proved of greater extent than was anticipated, and the coal seams crop out on the north side of the island. A cargo has already been dispatched, and it is possible to continue the export throughout the year. The Norwegian Government proposes to establish wireless and meteorological stations there.

AT Leonardsberg, four kilometres from Norrköping,

Digitized by Google

were known from this district, but the present one is the representation of a ship of a type hitherto unknown there, since it is not merely outlined but carved on the rock in low relief. About one metre long, it represents one of the so-called dragon ships, and belongs to the oldest group of such monuments of the Bronze age, a conclusion confirmed by its height of 32·5 metres above sea-level.

THE Y.M.C.A. is organising a series of microscopic exhibitions in the military and naval camps for the interest of the men in their leisure hours. An organising committee consisting of fellows and members of the Royal Microscopical Society, Quekett Microscopical Club, and the Photomicrographic Society has been formed, and already many fixtures have been made for exhibitions to be held in the Y.M.C.A. huts in various centres throughout the metropolitan area and the home counties. The exhibitions generally take place in the late afternoons or the evenings, and ladies and gentlemen who can spare the time to give service with their microscopes are invited to communicate with the hon. sec., Microscopical Department, Y.M.C.A., Tottenham Court Road, W.

SIR WILLIAM ASCROFT, a pioneer advocate of technical education, died on September 29, in his eighty-fifth year. He was president of the council of the Harris Institute, Preston, for more than thirty years (resigning in 1912), one of the original members of the council, and one of the trustees. The *Preston Guardian* remarks:—"Sir Wm. Ascroft's zeal for education, and particularly technical education, made the Harris Institute not only an incalculable benefit to Preston, but also one of the most influential pioneers of technical education in this country, setting an example which has been followed in many other centres. It was in recognition of his great services in this connection that his name was included in the list of Royal birthday honours in 1908."

IN the *South African Journal of Science* for June the Rev. S. S. Dorman deals with the question of the ruins at Zimbabwe and other sites in Rhodesia from the point of view of native tradition. He rejects the views advanced by Bent, Peters, and Hall that these buildings were erected by Semites, or under Semitic influence, from 2000 B.C. to A.D. 900. He has recorded the evidence of two intelligent natives, who allege that the buildings are of comparatively recent age, and that they were probably abandoned under pressure from marauding tribes. The so-called "temple" is now said to be only the residence of the chief, and the writer states that the buildings at Zimbabwe have not an appearance of antiquity, and that from the amount of weathering they do not appear to be more than 500 years old. He also produces evidence to show that gold mining was carried on by the natives at sites where these ruins do not exist, and he sums up by saying:—"As a large part of the Semitic theory of the origin of Zimbabwe and its associated ruins rests upon the ignorance of the natives of rock mining and the excessive antiquity of the mines, the bottom is absolutely knocked out of it by these and similar facts."

IN spite of the elaborate survey of Irish stone monuments by Mr. W. C. Borlase in his "Dolmens of Ireland," much remains to be done in that island, where dolmens, stone circles, alignments, and pillar-stones (inscribed, uninscribed, holed, and marked) are singularly abundant. In the June issue of the Journal of the Royal Society of Antiquaries of Ireland Mr. J. P. Condon publishes the first portion of a survey of the rude stone monuments of the northern portion of Cork County, in which he records many examples hitherto undescribed, and not even marked on the maps of the Ordnance Survey. At Greenhill a new ogham stone, with a fragmentary inscription, has been recently discovered; the Island group of monuments in the parish of Rahan forms a remarkable collection, and the stone circle at Lissard, in the parish of Grenagh, is fairly complete. On the whole, in this communication as many as eighty-five examples are described. This large collection from a small area shows the great abundance of these monuments, and the need for a complete survey of the whole of Ireland before these valuable antiquities are destroyed.

WITH the conception of the cancer problem as essentially a biological problem English readers have been familiar for many years, and Prof. L. Loeb's summary of the present position in the September number of the *Scientific Monthly* will be generally accepted. In several matters of detail, however, it is doubtful if his formulation of the problems will be useful. The attempt to separate the internal and external factors, as, for example, heredity and chronic irritation, disregards the fundamental truth that the influence of chronic irritation in the causation of cancer can only be conceived as acting through modification of the intracellular mechanism. It is a pity that the article does not distinguish between hypothetical views and generally accepted truths. An example of this is the statement that cancer of the mamma in mice cannot develop in the absence of a rhythmical repeated stimulus from the ovaries, although Loeb himself claims to have proved that the diminution of spontaneous mammary cancer in mice by castration can only be obtained if it is performed before sexual maturity. The contrast between spontaneous and transplanted cancer and the nature of immunity to the latter are well brought out. The paper ends with an attempt to combine the parasitic hypothesis of cancer etiology with the purely biological conceptions of its nature, mainly on the assumption that the explanation of the proliferation of cancer is to be found in analogies with the plant tumours caused by the *Bact. tumefaciens* and the bird tumours discovered by Peyton Rous to be due to a filtrable virus.

THE September issue of the *Journal of the Board of Agriculture* contains a useful summary of the results of co-operative experiments carried out in the years 1911–13, under the auspices of the Union of German Experiment Stations, with the view of obtaining further evidence as to the validity of the so-called "citric solubility" as a measure of the fertilising value of basic slag. The question is one which has aroused much controversy in recent years in Germany and also in this country, and has acquired considerable practical importance through the official recognition of the conventional Wagner method of determination of "citric solubility" in the Fertilisers and Feeding Stuffs Acts and regulations made thereunder. With one exception the reports from the five experiment stations co-operating in the tests are unanimous in upholding the validity of the Wagner test and justify the unanimous resolution of the Union of German Experiment Stations that there are no grounds for departing from the customary methods of evaluation of basic slag. It may be added that similar, though less comprehensive, tests carried out during the past three years at various centres in this country, under the auspices of the Agricultural Education Association, have also given results which in the main bear out this conclusion.

THE revised edition of Special Leaflet No. 46, recently issued by the Board of Agriculture and Fisheries, bears testimony to the vigorous criticism sustained from practical agriculturists since the first

Digitized by Google

issue by reason of the advocacy in the leaflet of the application of sulphate of ammonia to the wheat crop during the autumn months. In view of this criticism it has been thought desirable to embody in the new issue a reasoned justification of the recommendation. It is admitted that on the average of years, if a dressing not exceeding, say, ¾ cwt. sulphate of ammonia is to be used, spring dressing may be expected to pay better than autumn dressing. It is argued, however, that with wheat high in price much heavier dressings can be profitably applied, that these must in any case be given in two or more instalments, and that the best result may be expected from them if a portion be applied in the autumn and the balance in the spring. It is further urged that the common fear of loss of soluble salts by leaching throughout the winter is largely groundless in the case of sulphate of ammonia, since the ammonia is firmly retained by the soil and is only readily removed by water after conversion to the form of nitrate. Such nitrification being the outcome of bacterial activity, little change of ammonia is likely to take place at the low temperatures obtaining in the soil during the winter months.

THE attention of teachers of geography should be directed to the fine illustrations which are a feature of the *National Geographic Magazine*, published in Washington. The magazine is ostensibly a popular publication, and fulfils its object of increasing and diffusing geographical knowledge. The issue for August, 1916 (vol. xxx., No. 2), contains, among others, articles on Sardinia, Argentine and Chile, and San Domingo and Hayti. The chief feature of each article is the illustrations, many of which have considerable geographical value, and all of which are admirably reproduced. It is not easy to get illustrations of the negro republic of Hayti, and those in this magazine give a vivid impression of the island and its chief towns. The people of the countries concerned are well illustrated in all the articles.

ON the Monthly Meteorological Chart of the North Atlantic and Mediterranean for October there appears the usual inset map of "phenomenal drifts and heights" of North Atlantic ice. We notice in this map a record, which has appeared in many previous issues, of ice, presumably an iceberg, recorded near the island of Colonsay, off the Firth of Lorne, in the west of Scotland. It was sighted by fishermen in July, 1902. It is a little difficult to credit this remarkable occurrence, and if the fishermen were not mistaken the iceberg would surely have been seen by other observers, but the chart makes no mention of this. There are conditions of sea and weather in which ice can easily be imagined, and this suggests one of those cases. Unless the record is established beyond all doubt, it would be well to query this occurrence or to remove its indication from the chart.

WE learn from the *Geographical Journal* for September that the Arkhangel Society for the study of the Russian North is taking steps to obtain information as to the fate of the two Russian polar expeditions, of which there has been no news for several years. Rusanoff's expedition in the *Hercules* visited Spitsbergen in the summer of 1912, and was last heard of the same year in Novaya Zemlya, on its way through Arkhangel Society is raising a fund of 2500*l.* to be spent during the next three years in prizes for information throwing any light on the fate of the explorers. It is almost impossible that there can now be any survivors.

THE *Philippine Journal of Science* for January contains an interesting paper by G. W. Heise on the water supply of the city of Manila. The water is derived from the upper reaches of the Mariquina River, and the only physical purification it receives is storage in a reservoir for about three and a half days, which reduces the bacteriological count by about 90 per cent. The water is then treated with chloride of lime in doses varying from 0·5 to 0·75 part of available chlorine per million parts of water. This treatment appears to be still in a more or less experimental stage, and while, on the face of it, the sterilisation does not quite come up to expectations, some interesting results were obtained. Perhaps the most noteworthy of these is that the benefit derived from increasing the dose from 0·5 part of available chlorine per million to 0·625 part is very much greater than that derived by a further increase from the latter figure to 0·75 part. These results are chiefly judged by bacteriological counts made on the water before treatment and three-quarters of an hour after treatment. Possibly, if the results were judged on tests for *B. coli* done on various volumes of water (say 100 c.c., 10 c.c., 1 c.c., 0·1 c.c., etc.) instead of only on 2 c.c., and after longer contact (say three or four hours) of the water with the germicide, they would then wear a more favourable aspect, and at the same time give a truer estimate of the effect of the treatment.

UNDER the title "Mathematical Portraits and Pages" Messrs. Ginn and Co. have issued an attractive illustrated pamphlet of about twenty pages, drawn up by Prof. David Eugene Smith. The contents include reproductions of portraits of Newton, Isaac Barrow, John Wallis, Nicholas Saunderson, and Brook Taylor (of Taylor's theorem), also facsimiles of pages of "The Craft of Nombryng," Tonstall's "De Arte svppvtandi," Recorde's "Grovnd of Artes" and his "Whetstone of Witte," and the title-page of Digges and Son's "Stratioticos."

WHILE the late Captain Ferber was probably the first to consider lateral stability in applying the equations of rigid dynamics to the motions of aeroplanes, he unfortunately assumed that an aeroplane could be replaced by a system of three mutually orthogonal plane surface-elements, and it is greatly to be feared that the accident in which he lost his life may have arisen through the consequent misunderstanding of the problem. In the *Tôhoku Mathematical Journal*, ix., 4, Mr. Selig Brodetsky has now taken up the question as to how far it is possible, even on the simple "sine-law" hypothesis, to replace an aeroplane by three or more equivalent surfaces in three planes at right angles. The investigation leads to some exceedingly heavy algebra, which Mr. Brodetsky may claim to have worked out to the bitter end, with, briefly speaking, the following results:—(1) Except in the case of small divergences from a state of steady motion no such representation is possible; (2) in the

Digitized by Google

of logarithmic tables was invented and drawn up almost contemporaneously with Napier's work by Jost Bürgi, a Swiss. A brief note dealing with Bürgi's work is contributed to the *Mitteilungen der naturforschenden Gesellschaft in Bern* for 1914 (p. 318) by Dr. A. Bohren. Bürgi was born at Lichtenstein, in Toggenburg, about the year 1552, but of his early life little is known. He was originally a clockmaker by trade, but developed a talent for astronomical work, and, under the patronage at first of the Landgraf Wilhelm of Hesse, and later of Rudolf II. of Bohemia, he not only invented new astronomical instruments, but greatly assisted Kepler with his observations. His treatise on logarithmic methods described under the title "Arithmetical and Geometrical Progression-Tables" first saw the light in 1620, but it is certain that the tables were calculated and used by him long before that date, and their publication had been delayed by the war in Bohemia. Probably for the same reason the instructions which were to accompany the tables were never published, and in consequence they failed to come into general use. Both Bürgi and Napier built up their tables by forming successive positive integral powers of a number differing from unity by a very small decimal, but Bürgi's tables are based on the relations $x=10n$, and $y=10^8\ (1{\cdot}0001)^n$, while Napier calculated his logarithms from the successive powers of $1-10^{-7}$. It would thus appear probable that Bürgi was the first to use a base greater than unity, and so to obtain a scale more suitable for use with integral numbers. Whether Napier was acquainted with Bürgi's work is considered doubtful. Possibly Napier may have got the idea from Bürgi, and his choice of a system the base of which is less than unity may have been intended as an improvement to facilitate the use of the tables in trigonometry.

CIRCULAR No. 58 of the Bureau of Standards contains much valuable information as to the properties of invar and related nickel steels. Invar is a nickel steel containing about 36 per cent. of nickel, together with small amounts of carbon and manganese, and metallurgically negligible amounts of sulphur, phosphorus, and other elements. It melts sharply at about 1425° C. Above 200° C. to its melting point it may be considered to consist of a homogeneous solid solution of the above elements. Below 200° C., and at a temperature dependent on its history and exact composition, it undergoes a reversible transformation of such a nature that for any sample the transformation may be incomplete. This condition of thermochemical instability gives rise to both slowly and quickly changing values of its physical properties—changes which are particularly manifested in the expansion. It can be rolled, forged, turned, filed, and drawn into wires, and it takes a beautiful polish, giving an excellent surface on which fine lines may be ruled. It will withstand without spotting the corrosive action of water, even when immersed for several days. Its electrical resistivity is about eight times that of pure iron, and its temperature-coefficient of electrical resistance about 0·0012 per degree Centigrade. It is ferromagnetic, but becomes paramagnetic in the neighbourhood of 200° C. The coefficient of expansion, $\Delta h/h=-0{\cdot}00325\,.\,10^{-6}t^2$, holds for temperatures between 0° and 100° C.

THE results of the measurements of the rate of vaporisation of platinum vessels raised to high temperatures which have been made at the U.S. Bureau of Standards by Messrs. Burgess and Waltenberg are given in Scientific Paper No. 280, recently issued by the bureau. At temperatures below 900° C. there is no appreciable vaporisation, whatever be the composition of the platinum alloy of which the vessel is made. At 1000° C., however, the loss from 100 sq. cm. of a vessel of pure platinum is 0·08, and at 1200° C. 0·81 milligram per hour. For an alloy containing 1 per cent. iridium the corresponding rates are at 1000° C. 0·30, and at 1200° C. 1·2 milligrams per hour. For a 2·5 per cent. iridium alloy they are at 1000° C. 0·57, and at 1200° C. 2·5 milligrams per hour. Rhodium alloys, on the contrary, vaporise at lower rates. For an 8 per cent. rhodium alloy the rates of loss are at 1000° C. 0·07, and at 1200° C. 0·54 milligram per hour.

SINCE the appearance three years ago of the last edition of Prof. G. Lunge's "The Manufacture of Sulphuric Acid and Alkali," vol. i., many additions to the subjects treated of have been made. To deal with the new developments, Prof. Lunge has prepared a supplementary volume, which Messrs. Gurney and Jackson announce for publication this autumn.

MR. F. EDWARDS, of High Street, Marylebone, announces for early publication "The Fauna and Ethnology of New Guinea," being the official records of the collections formed by the British Ornithologists' Union Expedition, 1909–11, and the Wollaston Expedition, 1912–13, in Dutch New Guinea. The work will be in two volumes, and the edition limited to 150 copies.

## OUR ASTRONOMICAL COLUMN.

THE ASTRONOMICAL COMPASS.—The utilisation of the heavenly bodies as a means of determining direction has attracted considerable attention since the outbreak of war, and various attempts to simplify the problem for general use have been made. Simplified azimuth tables, in conjunction with maps of the stars, have mostly been employed, but it is evident that such tables may be replaced by graphical projections of the circles of the celestial sphere. Under the title of the "Rev. William Hall's Visible Astronomical Compass," an arrangement for the direct solution of the chief problems depending upon the diurnal motion of the heavens has been published by Mr. J. D. Potter, 145 Minories, E.C. (price 1*s.* net, post free). A circle 6 in. in diameter, on a card 10 in. × 8 in., contains a stereographic projection on the plane of the horizon, for latitude 50° N., showing the circles of each even degree of declination, and hour circles at intervals of ten minutes. Circles of azimuth and altitude are not drawn, but the outer edge of the horizon circle is graduated for true bearings, and altitudes may be read off on a scale provided, after measurement with dividers along a travelling thread fixed at the zenith point

Digitized by Google

EFFECT OF HAZE ON SOLAR ROTATION MEASURES.—The extensive determinations of the sun's rotation which have been made by the spectroscopic method have shown remarkable variations, even among results obtained at the same observatory at different times. Thus the values for the equatorial velocity range from 1·86 to 2·11 km. per sec., and observers have not agreed as to the inequality of the values obtained from different lines at the same time. Again, while some observers have found values of the rate of rotation progressively increasing with the wave-length, many other observations have not shown this effect. A valuable contribution towards tracing the source of such discordances has been made by R. E. De Lury, of the Dominion Observatory, Ottawa, in a careful investigation of the effects of haze on the spectroscopic measurements (Journ. R.A.S. Canada, vol. x., p. 345). The effect of terrestrial atmospheric haze is obviously to superpose a weakened solar spectrum, coming mainly from the centre of the sun's disc and showing no displacements at all, upon the limb spectra. The measured displacements of the blended lines at the limb would then be too small, and would vary from line to line, according to the character of the line at the limb as compared with the centre. Correction for the haze effect can be made by correlating accurate determinations of the relative strengths of haze and limb spectrum with displacements of groups of lines of different intensities. Further investigations may be necessary, but Mr. De Lury appears to be already convinced that variations hitherto ascribed to the sun are mainly due to variations in haze.

THE MASSES OF VISUAL BINARY STARS.—Mr. R. T. A. Innes has been led to some remarkable conclusions by a discussion of data relating to binary stars (*South African Journ. Sci.*, vol. xii., p. 453). All close pairs of stars, with few exceptions, are apparently to be regarded as binaries, whether they show relative motion or not. On the assumption that a binary has the same brightness as the sun, Mr. Innes calculates its distance from the apparent magnitude, and thence the mass, if the period be known. When no orbit has been computed, he proceeds in a similar manner, and calculates the annual angular motion at the distance of the companion which would be produced if the primary had the same mass as the sun. The calculated motion is mostly much in excess of that observed, and Mr. Innes concludes that very few double stars have a mass, or "gravitative power," as he prefers to call it, equal to that of the sun. He has been led to suppose that gravitative power is small in stars of types B and A, moderate in F, and large in G and K stars; in types Oe and M it appears to be absent altogether. The A type is considered to be poorly represented among binaries, because stars of this class have but little effective gravitative power, notwithstanding their great brilliancy. There appears to be a limiting distance below which double stars cannot exist, and for solar-type stars this is apparently about five times the earth's distance from the sun. It is suggested that light-pressure may partly or wholly neutralise gravitative power in stars of small density and great luminosity.

## MUTATION AND EVOLUTION.

tended, is more a chemico-physical than a biological phenomenon. Mutations, such as are observable in sponge spicules, in his opinion, strongly suggest the existence of definite factors in the germ plasm. The factorial hypothesis, he considers, is further supported by evidence which is accumulating as to the general course of evolution followed by the Tetraxonida. On the whole this evolution seems to have been progressive, accompanied by increasing complexity of structure, manifested especially in the skeleton. Along certain lines of descent, however, it appears that the culminating point has been passed, and regressive evolution is taking place, resulting in simplification of structure, by the dropping out of certain types of spicule. This loss cannot be regarded as an adaptive modification, nor can it be explained as due to mechanical necessities. Prof. Dendy concludes, therefore, that it is due to some change in the germ-plasm, affecting the power of the sponge to produce the particular spicules in question.

How can we reconcile these facts, it is asked, with the belief that evolution has taken place, in the main, by slow, successive modifications, rather than by sudden mutations? The conception of factors is intimately bound up with that of mutations, and the existence of the one would seem to imply the occurrence of the other.

As to which set of characters is to be regarded as the more important from the point of view of the student of progressive evolution Prof. Dendy holds there can be little doubt, but how far the division into adaptive and non-adaptive corresponds to the distinction between fluctuating variation and mutation is a different question. Certainly the chances are greatly against a mutation, when it first appears, having any adaptive significance. The evidence seems to him to show that the slow, successive variations of the Darwinian theory have had far more to do with the evolution of sponges than the process of mutation, and are mainly responsible, under the guidance of natural selection, for adaptive modifications.

It is not easy to follow Prof. Dendy in his attempt to discriminate between, and apportion the value of, adaptive and non-adaptive characters. It would seem, however, that he would regard the former as directly affecting viability, in proportion to their responsiveness to the demands of natural selection. They are characters which are of necessity immediately and continuously functional. The latter seem to be regarded as accretions or fortuitous variations, tolerated until they acquire survival value—that is to say, until they come under the sway of natural selection. If this is so, then all non-adaptive characters are potentially adaptive. They afford the basis for further evolutionary phases, or, in other words, the material which will determine the trend of future development and the fate of the organism for good or ill.

## SOME PROBLEMS IN EUGENICS.

STUDENTS of human heredity from the sociological point of view are indebted to the American Eugenics Record Office (Long Island, N.Y.). Its last-issued Bulletin (No. 15) contains the study of a family

Digitized by Google

in 1815, three generations being passed under review. Forty individuals are not recorded to have shown anti-social traits, but the remainder all failed in self-control, many being dishonest, and tending to alcoholism, or to profligacy, forty-one of these being "obviously a burden to society." These objectionable features were most pronounced in the case of offspring of a marriage of first cousins; Prof. Davenport's conclusion that violence of temper is a "dominant" character is confirmed, as in this family it was not found to "skip a generation." Most thoughtful readers of the bulletin will agree with the suggestion at the end of the preface that "unless society steps in and trains the trainable and segregates the uncontrollable, things will go from bad to worse."

Human endowments of a more pleasing kind are discussed by Dr. H. Drinkwater in a paper entitled "Inheritance of Artistic and Musical Ability," published in the last number of the *Journal of Genetics* (v., No. 4). He gives pedigrees—extending in some cases over four generations—of several families of artists and musicians, which indicate that where both parents are talented all the children inherit the talent, while a non-artistic or non-musical pair never have talented offspring. Hence he infers that artistic or musical ability is a recessive Mendelian character. When only one parent is musical, the number of children showing the recessive character may be more than the 50 per cent. required by the theory, but the records are too few for this to be regarded as a fatal difficulty to Dr. Drinkwater's interpretation. It will, however, be surprising if further research confirms the view that the complex nervous specialisation which must be supposed to accompany marked artistic or musical ability is determined by a simple genetic factor comparable with that which settles the colour of the eyes.

To the Journal of the Royal Statistical Society (vol. lxxix., part 2) Major Leonard Darwin contributes a paper on the inquiries needed after the war in connection with eugenics. He dwells on the selection of the best men generally for the fighting-line, shows that a higher death-rate may be expected to affect the more daring and self-sacrificing, and points out the meaning for the nation's future of the abnormally heavy losses among officers. His plea for a full investigation of the problem and of possible remedial measures may meet with a disappointing response, but nobody can read his paper and the report of the subsequent discussion—especially after studying the American bulletin summarised above—without realising the "reversed selective action" of the present world-conflict, and perceiving how absolutely opposed to the biological principles enunciated by Major Darwin's great father are those modern "people that delight in war."

## *THE BRITISH ASSOCIATION AT NEWCASTLE.*

### SECTION C.

#### GEOLOGY.

OPENING ADDRESS (ABRIDGED) BY PROF. W. S. BOULTON, D.Sc., F.G.S., PRESIDENT OF THE SECTION.

IF we attempt to compare the growth of applied geology in Britain with that, say, in the United States of America, or even in our great self-governing Dominions, or to appraise the knowledge of, and respect for, the facts and principles of geology as directly applicable to industry in these countries and in our own, or to compare the respective literatures on the subject, I think we shall have to confess that we have lagged far behind the position we ought by right of tradition and opportunities now to occupy. The vast natural resources of the countries I have named have doubtless stimulated a corresponding effort in their profitable development. But making due allowance for the fact that Britain is industrially mature as compared with these youthful communities, we cannot doubt that in this special branch of geology, however splendid our advances in others, we have been outstripped by our kinsmen abroad.

To attempt an explanation of this comparative failure to apply effectively the resources of geology to practical affairs would demand a critical analysis of the whole position of science in relation to industry and education which is being so vigorously debated by public men to-day. It is unquestionably due, in no small measure, to our ignorance and neglect of, and consequent indifference to, science in general, more especially on the part of our governing classes. This war, with all its material waste and mental anguish, may bring at least some compensation if it finally rouses us from complacence and teaches us to utilise more fully the highly trained and specialised intelligence of the nation.

Here I digress for a moment to lay stress upon a great and needless loss of valuable and detailed knowledge of our Coal Measure geology. It is well known that the Home Office Regulations demand that plans of workings in the different seams at a colliery shall be made and maintained by the colliery officials; and that on the abandonment of the mine copies of such plans shall be kept at the Mines Department of the Home Office for future reference. For ten years, however, they are regarded as confidential. Such information is recorded primarily with a view to the prevention of accidents due to inrushes of water and accumulations of gas.

Unfortunately, as mining men can testify, the plans are often woefully incomplete, inaccurate, and positively misleading as regards such features as faults, rolls, wash-outs, and so forth, and this is notoriously so along the margin of the plans where workings have been abandoned. Cases have been brought to my notice where plans of old workings have been consulted when adjacent ground was about to be explored, and afterwards the plans have proved to be grossly inaccurate, with the consequent risk of serious economic waste. I believe this unfortunate state of things is partly the effect of the complete official severance of the Geological Survey and the Mines Department of the Home Office. When the Geological Survey was first established, and for many years afterwards, a Mining Record Office for the collection and registration of all plans relating to mining operations was attached to it; but afterwards the Mining Record Office was transferred to the Home Office.

I would suggest that it ought to be made possible for all mining plans to be periodically inspected by Government officials with geological knowledge, not merely after the plans are deposited in a Government office, but during the working of the mine; so that, if desirable or necessary, the geological facts indicated by the mine-surveyor on the plan can be tested and verified. If accurate and properly attested plans of old workings were always available, the opening up of new ground would be greatly facilitated and much waste of time and money would be avoided.

#### *Need for Systematic Survey by Deep Borings.*

When we turn our attention to the possible extension of the Coal Measures under the newer strata of South-Central England, the geological data at our disposal are lamentably and surprisingly few. Notwithstanding our eagerness to unravel the difficulties, and so to open up new fields for mining activity, very little positive

Digitized by Google

progress has been made in the last twenty years. Of late a few deep borings have been sunk; one near High Wycombe, after piercing the Mesozoic cover, ended in Ludlow rocks; another at Batsford, in Gloucestershire, fifteen miles north of the well-known Burford boring, struck what are regarded as Upper Coal Measures, also resting on Silurian rocks.

At the present time it seems specially fitting to direct attention once again to our haphazard method of grappling with this great economic question. Are we to go on indefinitely pursuing what is almost "wild-cat" boring, to use the petroleum miner's expressive slang? Or shall we boldly face the fact that systematic exploration is demanded; and that this pioneer work is a national obligation, the expense of which should be a national charge?

At a meeting of the Organising Committee of Section C a recommendation was forwarded to the council in the following terms:—

"The council of the British Association for the Advancement of Science recommends that the site, depth, and diameter of every borehole in the British Isles exceeding 500 ft. in depth be compulsorily notified and registered in a Government office. That all such boreholes be open to Government inspection during their progress. That copies of the journals and other information relating to the strata penetrated by the boring be filed in a Government office under the same restrictions as those relating to plans of abandoned mines."

I would go further and urge that the Government should undertake the sinking of deep borings at selected points. This is no new idea. In his presidential address to the Geological Society of London in 1912 Prof. Watts pleaded most forcibly the vital importance of a State-aided underground survey of the area to which I have referred. The work is too vast for individual effort, or even for a private company to undertake. It is not suggested that deep borings should be sunk with the express purpose of finding coal. What is wanted is a systematic survey by borings at such spots as are likely to throw light upon the structural framework of the Palæozoic floor and the thickness of its cover.

Of course, there are difficulties in the way of such a scheme. There is the expense. But in view of the enormous economic possibilities of the work, and remembering that it is now possible to sink a boring to a depth of, say, 1200 ft., and to bring up 18-in. cores at a cost less than 2000l., it cannot be reasonably argued that the expense is beyond the nation's power to bear. A levy of a farthing a ton on the coal output of the United Kingdom for a single year would yield something like 300,000l., a capital sum that would provide in perpetuity an additional yearly grant to the Geological Survey of 15,000l., which would suffice not only to carry on this work, but would enable the Survey to extend its functions in the other directions I have indicated.

As to legal obstacles and vested mineral rights, I wish to say nothing except that if the country could be convinced that this work is urgently needed on national grounds, all scruples and doubts, so agitating to the official mind, would speedily vanish.

For many years I lived near our great exporting centres of the finest steam coal in the world, and as I watched the steady and incessant streams of coal-waggons, year in, year out, coming down from the hills, I was constantly reminded that we are rapidly draining the country of its industrial life-blood. Is it

*Chemical and Microscopical Investigation of Coal Seams.*

The recovery of by-products in the coking of coal, which up to the beginning of the war was almost exclusively undertaken by the Germans, is likely in the future to become an important British industry. This will ultimately demand a thorough knowledge of the microscopic and chemical structure of all the important coking seams in our coalfields.

Remembering how varied both in microscopical structure and chemical composition the individual laminæ of many of the thick coal-seams are, it will readily appear how important such a detailed investigation may become, having regard to the great variety of these by-products and their industrial application. Moreover, thin seams, hitherto discarded, may pay to be worked, as may also an enormous amount of small coal, estimated at from 10 to 20 per cent. of the total output, which up to the present has been wasted.

*Geology of Petroleum.*

It has been frequently remarked that in order to account for the vast accumulation of coal in the Carboniferous strata, it is necessary to postulate a special coincidence over great areas of the northern hemisphere of favourable conditions of plant growth, climate, sedimentation, and crustal subsidence, conditions which, although they obtained at other geological periods over relatively small areas, were never repeated on so vast a scale. Having regard to the estimates of coal deposits in Cretaceous and Tertiary strata, published in our first international Coal Census, the "Report on the Coal Resources of the World,"[1] it would appear that we might reasonably link the Cretaceo-Tertiary period with the Carboniferous in respect of these peculiar and widely prevalent coal-making conditions. For I find that of the actual and probable reserves of coal in the world, according to our present state of knowledge, about 4½ million million tons of bituminous and anthracite coal exist, the vast bulk of which is of Carboniferous age; while there are about 3 million million tons of lignites and sub-bituminous coals, mostly of Cretaceous and Tertiary age.

When we look to the geological distribution of petroleum, we note that it is to be found in rocks of practically every age in more or less quantity, but that it occurs *par excellence*, and on a great commercial scale, in rocks of two geological periods (to a smaller extent in a third); and it is significant that these two periods are the great coal-making periods in geological history—the Carboniferous and the Cretaceo-Tertiary. It would take me beyond my present purpose to explore the avenues of thought and speculation opened up by this parallel. I will only remark that it seems to afford some support for the view that coal and petroleum are genetically as well as chemically related. While the terrestrial vegetation of the two periods was accumulating under specially favourable physiographical conditions, ultimately to be mineralised into seams of coal, the stores of petroleum believed to be indigenous to strata of the same periods were probably derived from the natural distillation of the plankton which must have flourished, too, on an enormous scale in the shallow, muddy waters adjacent to this luxuriant land growth. The phytoplankton, including such families as the Diatomaceæ and Peridiniæ, may well have played the chief *rôle* in this petroleum formation, while affording unlimited sustenance to the small and lowly animal organisms, like

Digitized by Google

that a prodigious development of a new and vigorous flora during both periods—the spore-bearing flora, in the main, of the Carboniferous, and the seed-bearing flora of the Cretaceo-Tertiary period—was the chief contributory factor in the making of the world's vast store of solid and liquid fuel. It contributed directly by supplying the vegetable matter for the coal, and indirectly by stimulating the development of a prolific plankton, from which the oil has been distilled.

The world's production of petroleum has trebled itself within the last fifteen years. In 1914 the United States of America produced 66·36 per cent., and North and South America together nearly three-fourths of the world's total yield; while the British Empire (including Egypt) produced only a little more than 2 per cent. In the near future Canada is likely to take its place as a great oil- and gas-producing country, for large areas in the Middle-West show promising indications of a greatly increased yield. But Mexico is undoubtedly the country of greatest potential output. Its Cretaceous and Tertiary strata along the Gulf Coastal Plain are so rich that it has been stated recently on high authority that "a dozen wells in Mexico, if opened to their full capacity, could almost double the daily output of the world."[2]

As is well known, natural supplies of petroleum are not found in the British Isles on a commercial scale; but for many years oil and other valuable products have been obtained from the destructive distillation of the Oil Shales of the Lothians. If Mr. Cunningham Craig is right in his views recently expressed,[3] these shales, or, rather, their associated freestones, have been nearer to being true petroliferous rocks than we thought; for he believes that the small yellow bodies, the so-called "spores" in the kerogen shales, are really small masses of inspissated petroleum, adsorbed from the porous and once petroliferous sandstones with which the shales are interstratified.

If recent experiments on peat fulfil the promise they undoubtedly show, we shall have to take careful stock of the peat-bogs in these islands. It is well known that peat fuel has been manufactured in Europe for many years. But my attention has been called to a process for the extraction of fuel-oil from peat which has been tried experimentally in London, and is now about to be launched on a commercial scale, utilising our own peat deposits, like those of Lanarkshire and Yorkshire.

The peat is submitted to low-temperature distillation at ordinary pressure, or at a slight negative pressure, the highest temperature reached being about 600° C. From a ton of Lanarkshire peat, after the moisture is reduced to 25 per cent., 40 gallons of crude oil, 18 to 20 lb. of ammonium sulphate, about the same quantity of paraffin wax, 30 to 33 per cent. of coke, and 5000 to 6000 cubic ft. of combustible gas are obtained. The coke is said to be of very good quality. By the same process it is hoped to get satisfactory results from the lignites of Bovey Tracey.

Considering the rapid development of oil as fuel, and its supreme industrial importance in many other ways, it is remarkable that British geologists should have given such little attention to the *origin and occurrence of petroleum*. Among American geologists a lively Survey, offered in 1910[4] a simple explanation of the occurrence of petroleum, based upon his own observations in Burma, a research which seems to have attracted far more attention in America than in this country. He showed that the oil of the streams and swamps in Burma is carried down to the bottom of the water in small globules by adhering tiny particles of mud. Thus there is formed a deposit of mud containing globules of oil and saturated with water. If afterwards this deposit is covered by a bed of sand, the oil and part of the water, as the pressure of overlying sediment increases, are squeezed into the sand, so that by a repetition of the process a petroliferous series of clays and sands may be accumulated. In examining lately a large quantity of the well-known "landscape marble" from the Rhætic of Bristol, I obtained from it small but appreciable amounts of petroleum; and towards the end of my investigation I was pleased to discover that I was in thorough agreement as to the origin of this curious landscape structure with Mr. Beeby Thompson, whose research was published more than twenty years ago.[5] In these thin deposits of hydrocarbons among laminated silts, with their striking tree-like growths and hummocky surfaces, may we not have, in miniature, an illustration of the deposition and partial migration of petroleum which occurs on so vast a scale in the oilfields of the world?

It is not suggested that all petroleum deposits have had such an origin. I am convinced, however, that in all geological ages such sedimentary accumulations have occurred; and that, except where the conditions of cover have been favourable for its imprisonment, the oil is, and has been throughout geological time, incessantly escaping at the surface. Thus we may conceive the earth as continuously sweating out these stores of oil, either in the liquid or gaseous form, especially where rocks are being folded and rapidly denuded.

It is sometimes asked whether the adoption of mineral oil as a power-producer is likely to supplant coal, and thereby seriously reduce the output of that mineral. The world's yield of petroleum will doubtless go on increasing at a very great rate; but from the experience gained in some of the fields in the United States and eastern Canada, it seems unlikely that this increase can continue for a very long period. Practically complete exhaustion of the world's supply is to be looked for within 100 years, says one authority.[6] Even if the output rose to ten times the present yield, it would represent only about half the present world output of coal, and it is practically certain that so high a yield of oil could not be maintained for many years. Owing to the almost certain rapid increase in the output of coal, estimates made by the same authority indicate that the total production of petroleum could never reduce the world's output of coal by more than about 6½ per cent.[7]

For us, and probably for those of the next generation, the geology of petroleum will continue to be of immense practical importance; but coal will doubtless remain our great ultimate source of power.

An obligation rests upon us to see that the oil resources of the British Empire and of territories within our influence are explored, if possible by British geologists, with all the special knowledge that can be

Digitized by Google

*Organisation of Expert Knowledge.*

We are reminded by the report of a Royal Commission—that on Coast Erosion in 1911—that systematic observations and the collation and organisation of geological and engineering knowledge are urgently needed in connection with the protection of our coasts and the reclamation of new lands. For it will be remembered that the Commission found that during the last thirty-five years the gain of land, as shown by Ordnance Survey maps, has been more than seven times the loss by erosion.

Here, again, the British Association may reflect with pride that it paved the way for this national inquiry. For many years its Committee on Coast Erosion gathered and collated evidence on erosion, and induced the Admiralty to instruct the coastguard to observe and report upon changes that take place from time to time.

After recommending "that the Board of Trade should be constituted the Central Sea-Defence Authority for the United Kingdom for the purpose of the administration of the coast-line in the interest of sea defence," the Commissioners go on to urge that "that Department should have the assistance of scientific experts to collate information and to secure systematic observations with regard to questions such as the changes taking place below the level of low water, the travel of materials in deep water, the movements of outlying sandbanks, etc., which are continually happening on the coasts of the kingdom, and with regard to which the information at present is scanty and vague."[1]

In economic geology, as in the case of other applied sciences, we must rely in the future less upon chance individual effort and initiative. We must concentrate, centralise, and organise; and at every stage we shall need expert control and advice as regards those larger scientific issues of national importance which have a direct practical bearing.

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

LEEDS.—The annual report of the Department of Coal, Gas, and Fuel Industries, of which Prof. J. W. Cobb occupies the chair as Livesey professor, has just been issued by the University. It begins with a reference to the number of students who have entered the Army or are connected with the war work of the department, and also to the election of candidates to the recently founded Corbet-Woodall scholarship and Arthur Walker exhibition. Courses of lectures, which have been given in the past by specialists connected with the gas and fuel industries, have had to be restricted owing to the demands made by the war upon the lecturers. The research work of the department during the year includes two important publications. The Ventilation Research Committee, representing the Institution of Gas Engineers, has issued its third report. The work has been carried out, as before, by Mr. W. Harrison, who has made a careful and interesting study of causes of down-draughts, the effect of ventilating burners, etc. The second research, by Prof. Cobb and Mr. H. Hollings, on "Thermal Phenomena in Carbonisation," was read before the undergoing modification and extension in order to cope with the increased demand for chemists trained to take up industrial posts. Commencing at first with a two-year curriculum, the courses have in recent years been extended over a period of three years, and in many instances students have, with profit to themselves, continued their advanced studies into a fourth year and even longer. If the renascence of British chemical industry is to be fruitful, there will not only be a demand for more chemists, but it will be essential that these newcomers should be better trained than their predecessors. The Executive Committee of the City and Guilds of London Institute has placed at the disposal of the chemical department of the Finsbury college a new suite of rooms, to be fitted as advanced laboratories of applied chemistry. The work of adaptation is in full progress, and the laboratories will be sufficiently ready for advanced students early in the new year. The installation of technical appliances is being extended, partly by purchase and partly by construction in the chemical department. Factory methods of conducting filtration, evaporation, distillation, desiccation, heating under pressure, and other generalised processes will be studied, and the possession of this plant and apparatus will render possible the execution of industrial researches in many branches of inorganic and organic chemistry, as, for example, the extraction of metals, preparation of alloys, cements, glazes, porcelains, glass, enamels, pigments, synthetic dyes, artificial perfumes, and pharmaceutical products. One gratifying feature of this development is the fact that the effort to develop along industrial lines is so far appreciated by certain firms that they have assisted by gifts of plant and chemicals.

IN a pamphlet of thirty-six pages, entitled "Scientific Method in Schools" (Cambridge University Press, price 1s.) Mr. W. H. S. Jones, senior classical master at the Perse School, has put forward some well-timed suggestions upon a subject now universally admitted to be of first-rate importance. Starting from the assumptions (1) that all subjects, in different ways and to different degrees, can be made to give a training in scientific method, and (2) that the scientific training even of the future researcher in physics or chemistry will be more effective if it is not confined to his special subject, but rests on a broad foundation, he puts forward the thesis that "whatever subjects are included in the curriculum, each one should contribute its quota to a comprehensive scheme of scientific method." He does not demand a strict "heuristic" treatment of every subject, but maintains that in lessons occurring regularly "once a week or once a fortnight in each subject," the pupil should be confronted with problems to be attacked by strict application of the methods of deduction and induction—particularly the latter—and should be taught to be constantly conscious of the necessity of working according to fixed laws. Mr. Jones introduces his proposals by quotations from Cicero and Charles Lamb, but does not show whether he is aware how entirely they are congruent with the results of the best relevant psychological researches of the present day. Be that as it may, the practical teacher will be more directly interested in the eleven detailed examples, drawn from courses in languages, history, geography, biology, and mechanics, which the

Digitized by Google

On Monday, October 2, her Majesty the Queen opened the extension of the science laboratories of the London Royal Free Hospital School of Medicine for Women. The ceremony took place in the anatomical department, where more than 600 guests were accommodated. The Queen was addressed by the dean of the school, Miss Aldrich Blake, M.D., who gave a brief account of the school, comparing its position in 1874, when it was founded by Dr. Sophia Jex-Blake, with a total of fourteen students, and its present condition, with splendidly equipped laboratories and more than 400 students; by Dr. Winifred Cullis (lecturer in physiology), who thanked the Queen for the interest she had shown in the work and education of medical women, and all those who by their help had made it possible to carry out this much-needed extension; and by the chairman of the council, who, having handed to the Queen a key presented by the architects, asked her to open the extension. After the Queen had declared it open, her Majesty made a tour of the new laboratories. The extension which has now been carried out was planned and arranged for before the war, owing to the steadily increasing annual entry of students. When war broke out it was for a time uncertain whether the extension should be proceeded with, but the number of students entering the school in 1914 was so great that there was no alternative. Consequently an appeal for 30,000*l.* was issued, the appeal was generously responded to, and within seventeen months the whole sum was obtained. On the top floor the whole extension is given to the anatomical department, which now has one of the finest dissecting rooms in the country (an excellently lighted room, 140 ft. in length), private rooms, demonstration room, preparation rooms, and mortuary. The next floor is given to the physiological department, and the extension provides an advanced laboratory, demonstration theatre, dark-room, storeroom, and private and research rooms. In the floor below is an extension of the chemical department, adding to it an organic laboratory, balance room, and private and research rooms; on this floor is found also a students' union room. Below this is the extension of the physics laboratory, including lecture room, dark-rooms, and research room, and also some laboratories for pathological research.

# SUCCESS !

If success in your experiment is dependent upon the Filter Paper, it may be commanded by the use of Whatman Filter Paper.

**For all general filter purposes use Nos. 1-5. There are at present Four Acid Extracted grades (practically ashless); two more, Nos. 43 and 44, are in preparation.**

## WHATMAN FILTER PAPER

**No. 1.** Equivalent to C.S. & S. 595.

**No. 2.** Equivalent to C.S. & S. 597.

**No. 3.** Equivalent to C.S. & S. 598.

**No. 4.** Equivalent to C.S. & S. 604.

**No. 5.** Equivalent to C.S. & S. 602.

**No. 30.** Hydrochloric acid treated. Low ash, close texture. For quantitative work. **Equivalent to DREVER-HOFF 207.**

**No. 40.** A paper treated by both Hydrochloric and Hydrofluoric acids. Has less ash than No. 30. For very accurate quantitative work. Retains finest precipitates. **Equivalent to C.S. & S. 589.** (White Ribbon.)

**No. 41.** Treated same as No. 40, but more open and filters more quickly. Not recommended for filtering very fine precipitates unless properly precipitated. **Equivalent to C.S. & S. 589.** (Black Ribbon.)

**No. 42.** A new grade, resembling Nos. 40 and 41 in chemical qualities, but differing in its physical properties, being much harder and extremely close in texture. Suitable for use in filter pumps. **Equivalent to C.S. & S. 589.** (Blue Ribbon.)

**Nos. 43, 44 and 50, also Folded Filters and Fat Extraction Thimbles, will be out shortly.**

NOV 1 1916

THURSDAY, OCTOBER 12, 1916.

## BRITISH FORESTRY.

*British Forestry: Its Present Position and Outlook after the War.* By E. P. Stebbing. Pp. xxv+257. (London: John Murray, 1916.) Price 6s. net.

THIS book, by the Lecturer in Forestry at Edinburgh University, is a study of the various problems which are involved in making provision for adequate supplies of timber after the war. In time of peace we were dependent on foreign countries for the great bulk of the timber, paper pulp, and other forest products which we consumed, the annual import into the United Kingdom being valued at no less than 43,000,000*l.* in 1913. During the war, owing to cessation of exports from the Baltic and lack of shipping generally, our supplies of timber have been much curtailed, although our need is now greater than ever. The trenches, railways, and other military works at the front have used up vast quantities of timber; while our collieries and mines have not abated their demand for pitwood. We have been forced to draw largely on our own woodlands, which are rapidly being felled under the auspices of the Home-grown Timber Committee, appointed by Government some months ago. The preservation and restoration of the existing woodland area call for immediate consideration.

Mr. Stebbing's remedy, which is developed in some fifty pages, is a national planting scheme to be taken in hand immediately. The recommendations of the various Government Committees and Commissions on Forestry since 1887 are shown to have had little effect. With regard to the existing woodland area, Mr. Stebbing demands that "all woods purchased and felled by Government at the present high rates should be at once replanted by the owner, as a condition of the contract." His planting scheme includes, in addition to the renovation of the woods that are now being denuded, the planting of 5,000,000 acres of wasteland, the whole to be carried out in thirty-two years, roughly equivalent to the taking in hand yearly of about 200,000 acres. A planting plan should be drawn up, county by county, under which the felled-over areas, the woods consisting mainly of useless scrub, and the most accessible of the wastelands would be selected and the order of planting laid down. The land might be acquired in many cases by lease or purchase. In other cases the Government, going into partnership with the landowner, might provide the money for planting and fencing up to a prescribed sum per acre. Compulsory powers to purchase wasteland, and enforced management of privately owned woods, according to plans approved by a State Forestry Board, though necessary if great progress in forestry is aimed at, are not distinctly advocated in this book.

The question of labour is discussed at length, two chapters being devoted to the employment of women, whose services might be useful in forest nurseries. At the end of the war partially disabled soldiers and sailors will be available, as well as a large number of ordinary labourers. The work could be commenced immediately by utilising the expert woodmen from among our prisoners; and thousands of acres of our denuded woods could be replanted during the coming winter.

Mr. Stebbing has made a special study of the timber trade and forests of Russia, Finland, and Siberia, and devotes a hundred pages to this subject. The immense supplies of timber available in this vast territory are of great importance to the Allies, in view of the reconstruction necessary at the end of the war in the devastated districts of Belgium, France, Serbia, and Poland. Mr. Stebbing urges the British Government to lease large areas in the Crown forests of Russia, which we could work in the period following the war, and thus obtain what timber we require at a reasonable cost. This measure would seem to be of doubtful utility, as it is probable that all the accessible forests (those near rivers where timber can be felled profitably) are already taken up.

## CHEMICAL WATER PURIFICATION.

*Water-Purification Plants and their Operation.* By M. F. Stein. Pp. viii+258. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1915.) Price 10*s.* 6*d.* net.

THIS volume is another addition to the already large number of books on water purification coming from the United States; and while, perhaps, the subject is not treated in quite such a scientific manner as in some of the others, there is a quantity of concise information useful to one who is in charge of a modern water-purification plant, and particularly of one where chemicals are used.

To anyone acquainted with methods of water purification as usually practised in this country the book will show vividly the wide differences existing not merely between the problems that present themselves to water undertakers in Britain and America, but still more their different methods of dealing with them. In this country slow sand filtration, usually preceded by more or less lengthy storage, is the general rule, while in America the usual methods appear to be rapid mechanical filtration after the addition of chemicals for coagulating, sterilising, or softening purposes. This is probably due to the fact that to a large extent the water used in the United States is derived from the great rivers and lakes, and is often very turbid and sometimes highly polluted, whilst over here many of the large towns obtain their supplies from upland gathering grounds, where the water is impounded in large lakes or reservoirs away from any chance of serious pollution, and only a com-

Digitized by Google

paratively few towns are supplied from polluted rivers. Another reason may be that in this country there is still a popular prejudice against the chemical treatment of a drinking water which is probably not nearly so marked in America.

As is usual with works on water purification, the book opens with a chapter dealing with the sources of supply and impurities likely to be found in water from different sources. The next chapter, and by far the longest, deals with types of purification plants, and describes in some detail the works of several large American cities, which may be taken as typical of the others.

Chapters follow on physical and chemical tests, bacterial tests, and the interpretation of these tests. In these chapters the author goes into very minute detail on the methods of carrying out these tests. It is worthy of note that no mention is made of chemical tests for organic impurities, the author confining his attention to tests for such substances as affect the dose of chemicals to be added—*e.g.* alkalinity and $CO_2$—and the estimation of any excess of the chemicals added. This is certainly at variance with the usual practice of English water analysts. Another point is the method suggested for the detection of *B. coli* in water, which is quite different from that usually adopted in this country, and scarcely seems to be capable of being used with any great degree of certainty, depending as it does on the relative proportions of $CO_2$ and hydrogen formed by the fermentation of dextrose broth. One cannot but feel that it is not altogether desirable that persons other than qualified chemists and bacteriologists should be entrusted with the carrying out of these tests on water, especially when, as in this case, the descriptions are given by an engineer.

The best part of the book is what follows in chapters dealing with coagulation and sterilisation, water softening, and sedimentation. These subjects are clearly and fully treated, and the chapters contain a host of valuable information.

The last chapter consists of notes on filtration and general operation. Next follow some very ingenious charts for computing the results of analyses and the amounts of chemicals required according to the analysis of the water. These charts, however, are on rather too small a scale to be of much practical use. The work concludes with appendices dealing with the analysis of coagulants, standard solutions, specifications for coagulants, and one or two useful tables.

The book is decidedly limited in its scope, and deals with only a few of the modern methods of purification, and, indeed, entirely omits to mention several important processes introduced in this country during the last decade. For example, no mention is made of either Houston's Excess Lime method of sterilisation and softening or the use of such substances as Permutit.

The volume is clearly printed and profusely illustrated with diagrams and photographs.

DENISON B. BYLES.

## THEORY AND EXPERIMENT.

*A Text-Book of Practical Physics.* By Dr. H. S. Allen and H. Moore. Pp. xv+622. (London: Macmillan and Co., Ltd., 1916.) Price 8*s.* 6*d.* net.

THE distrust which the "practical man" feels for science is well known, and it must be confessed that he is by no means alone to blame for his attitude in the matter. The fault lies to some extent with the teacher of science, who too often lays undue stress on the theory, and, if an experiment which is supposed to illustrate the theory does so but indifferently, the student is apt to get the impression that theory and fact are somewhat distantly related. For example, a student who, having been rashly told that Atwood's machine is used for measuring "g," finds by careful experiment that the value obtained differs more or less widely from that given in text-books, generally concludes that the experiment is "wrong." He rarely has sufficient confidence in his work to know that the experiment cannot be wrong, and that it is the theory which is at fault. Of course, the trouble lies in an insufficient realisation of the assumptions made in the theory. If the experiment does not agree with theory, the student should be taught to find the cause of the discrepancy and to estimate the degree of concordance which the limitations of the theory and the accuracy of his measurements may lead him to expect. It is of the utmost importance that such discrepancies should not be passed over; and in a book like that before us, in which theory and experiment are brought together, the valuable introductory note on the accuracy of observations might with advantage have been amplified.

The course covered is a very complete one (up to about Pass B.Sc. standard), and we are glad to see that a fair share of attention has been devoted to mechanics. The electrical section, also, is very full, and has a valuable chapter of notes on electrical apparatus. An appendix contains mathematical tables and an assortment of useful data which are constantly being required in a physics laboratory. The book is convenient in size, well arranged, well illustrated, and well produced, and there are remarkably few misprints.

Each experiment is preceded by a brief theoretical account of the principles involved, which should enable the student to acquire an intelligent appreciation of the experiment to be performed; but in some cases scarcely sufficient attention is directed to the possible experimental errors.

There are occasionally statements which might prove misleading. We cannot, for example, agree that "the truth of Archimedes' principle can be demonstrated readily by purely theoretical methods." Such a statement tends to conceal the purely experimental foundation of the principle.

In the optical section "pin methods" receive perhaps more attention than they deserve, and in some cases they might with advantage be replaced by the more accurate and quicker "line methods." We should also like to have seen a description of

Digitized by Google

the standard Pentane lamp instead of the vague statement that "some other standardised source [than the standard candle], such as a Pentane lamp, is used," without any indication of the way in which such standardisation is effected. We are glad to note, however, that Swan is given due credit for the prism-photometer, the origin of which is usually concealed so effectively under the name Lummer-Brodhun.

In dealing with methods of measuring the co-efficient of linear expansion of a solid, the authors are scarcely fair to the optical lever, which is described as "not at all accurate": we should say that much depends upon the experimenter! The attention of the student might also have been directed to the fact that all these methods give only the difference between the expansions of two bodies, one of which is supposed not to expand. On p. 336, in the experiment on expansion of air at constant pressure, mention should have been made of the error due to the saturated water vapour in the flask. The experiment given on p. 357 to illustrate Newton's law of cooling will fail to do so unless the top of the calorimeter is closed; and the statement on p. 383 that "if the air is cooled down *locally* to this temperature [the dew-point] dew will be deposited on any flat surface exposed to this cooled air," requires modification.

In the section on magnetism we are sorry to see the statement (p. 393) that "a magnet of any shape usually behaves as though forces of attraction or repulsion originated from two definite points in its substance, which may be termed its poles." Careful experiment soon convinces an intelligent student that a point pole is a fiction. Again, on p. 426, it would be well to point out that the tacit assumption that the moments of the two magnets are unaltered by their mutual action when in close proximity is not justified by experiment.

In reference to the determination of the efficiency of an electric lamp, attention is rightly directed to the fact that this should be expressed as candle-power per watt, and not watts per candle-power.

The book as a whole is a valuable addition to the list of text-books on practical physics, and the authors show an intimate acquaintance with the difficulties of both students and teachers which should make it very acceptable to both.

G. A. S.

## SYSTEMATIC ZOOLOGY.

(1) *The Fauna of British India, including Ceylon and Burma. Rhynchota*: vol. vi. *Homoptera*: Appendix. By W. L. Distant. Pp. viii + 248. (London: Taylor and Francis, 1916.) Price 10*s*.

(2) *Catalogue of the Ungulate Mammals in the British Museum (Natural History)*. Vol v.: *Perissodactyla (Horses, Tapirs, Rhinoceroses), Hyracoidea (Hyraxes), Proboscidea (Elephants)*. By the late Richard Lydekker. Pp. xlv + 207. (London: Printed by Order of the Trustees of the British Museum. Sold by Longmans and Co., 1916.) Price 7*s*. 6*d*.

(1) MR. DISTANT'S Appendix to the account of the British Indian Homoptera in the admirable "Fauna" has plenty to chronicle in the shape of novelties. In the Cicadas, so striking a group in the warm regions of the earth, he has to record as many as twenty-three new species since he dealt with the family in vol. iii.; and naturally among those families which make less noise in the world the proportion of novelties is greater, even the little Jassidæ claiming thirty-two new forms, and the Cercopidæ, familiar to us in the person of the "cuckoo-spit" insect, as many as fifty, a number more than trebled by the Fulgoridæ, most of which are not large and conspicuous like the celebrated "lantern-flies" which popularly typify the family. The Membracidæ have more than sixty new forms described, which fully bear out the family reputation for eccentricity in thoracic appendages. Among the new forms described there is a large proportion of new genera, which are fully characterised, so that it is not surprising that the present volume is a fair-sized one; it is well illustrated, having 177 figures.

(2) In addition to the Perissodactyles, Elephants, and Hyraxes, this concluding volume of the British Museum Ungulates contains an appendix to the Bovidæ, the general systematic index, and the index to the whole work. It has naturally suffered by the death of its author before he could revise, or indeed even complete, it; thus the lists of specimens in the museum do not go beyond the Horses and Tapirs, though in the remaining families the synonymy and localities are given. We are told that it has not been thought advisable to complete the volume on the full original plan, partly for lack of a competent author and partly for fear of detriment to science resulting from a mixed responsibility. It seems a great pity, however, that descriptions were not added throughout, as the responsibility difficulty could surely have been got over by bracketing and initialling them; while it does not conduce to the credit of science to issue a work dealing with such important and generally interesting animals with its last volume disfigured and rendered half useless by their general absence. Some can be found in the accounts of the Hyraxes and of the Bovines in the Appendix; in the case of the one equine described, *Equus quagga cuninghamei*, the description is made misleading by the figure being incorrect, since it is said to have the mane well developed, while the animal figured has scarcely any. This is one of the "Burchell's Zebra" subspecies, all of which, we think reasonably, are treated as forms of the Quagga, the typical race of which is extinct; but the Kiang, Chigetai, and Onager are given full specific rank. There are thirty-one illustrations in all, exclusive of an excellent portrait of Lydekker which forms the frontispiece.

## OUR BOOKSHELF.

*An Introductory Course of Continuous-current Engineering.* By Dr. Alfred Hay. Pp. xii+360. Second edition, revised. (London: Constable & Co., Ltd., 1916.) Price 6*s.* 6*d.* net.

LIKE all Dr. Hay's books, the present work will well repay the elementary student for the time spent on its study. It first treats of the elementary laws of electromagnetics, then proceeds to deal with instruments, machines, secondary cells, electric lamps, switchgear, and conductors. In places it lacks depth, whilst such things as definitions, fundamental ideas, and the distinction between E.M.F. and P.D. are not quite so clear as they might be.

The chapter on armature windings could be improved. The statements made regarding wave-windings have the ordinary two-circuit four-pole winding in view, and one at least of them is not even universally true for this. It is a mistake to hide from the student that many other wave-windings are possible, especially as some of them have practical advantages which will lead to their more extended use in future.

The chapter on storage cells ought to have at least one illustration showing a complete cell or battery, and the diagrams showing the construction of the plates might have been of a more modern type. The really useful primary cells should surely have found a place in "Continuous-current Engineering."

The chapter on switchgear is to be especially commended, as it gives much more information than is usually found in a small general text-book.

Although we have criticised several details, we are pleased with the book on the whole, and can recommend it to those requiring an elementary book on the subject. DAVID ROBERTSON.

*My Yoruba Alphabet.* By R. E. Dennett. Pp. xi+45. (London: Macmillan and Co., Ltd., 1916.) Price 1*s.* 6*d.* net.

THOSE who have been accustomed to depend upon the classical work of Col. Ellis on the Yoruba people may be surprised at Mr. Dennett's speculations. Ellis, a careful, competent writer, tells us that they worship a pantheon of nature deities, like Olorun, the sky-god, and phallic gods of fertility, like Elegba, to whom human sacrifices in a brutal form were, or are, offered. Of their higher spirituality he gives little or no evidence. Mr. Dennett, a competent philologist, starting from his own "firm conviction that all the works of the Great Creator of the Universe . . . conform to one definite universal order, and that the spirit, or inner consciousness of man, moves in conformity to this universal order so long as that consciousness works in obedience to the dictates of its Great Author," finds beliefs of a similar type among the Yorubas, who "are by nature deeply religious." Their alphabet, as interpreted by him, expresses eight "Elemental Factors," such as Authority, Morality, Potentiality, and so on. He claims that the summary of his results "should establish decisively and conclusively the systematic conformity of the construction of Yoruba words—especially the Yoruba primitive verbs—with the eight elemental factors of the Great Universal Order." Whether the hypothesis meet with acceptance or not, Mr. Dennett's book will be useful to students of the Yoruba speech, and, in particular, the system of transliteration now proposed deserves careful consideration.

*Bacon's War Maps. Europe, embracing all the Countries Involved.* (London: G. W. Bacon and Co., Ltd., n.d.) Price 6*d.* net.

THIS folding war-map includes the greater part of Europe and is on a scale of 1 : 4,000,000. It is politically coloured, fairly clear, and has a large number of names, but the only attempts to show relief is by a few stray caterpillar heights. In elevated areas like the Alps and the Carpathians these serve some purpose on a small-scale map like this, but in a lower region, such as the Allies' western front, the few heights that are shown are more misleading than useful. In the Balkans the map fails to reveal the significance of the Vardar valley. Nor is there any attempt to show marsh lands, the military importance of which has been demonstrated on more than one front. In the matter of names there is some scope for criticism. Halicz is not marked and Gorizia appears in the unusual form of Gorz. The map leaves scope for many improvements, which might have been carried out at the expense of the somewhat glaring political colouring if cost was a first consideration.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### Science in Education.

PERMIT me to suggest that the science of man is scarcely "a vicious circle of introspective examinations," but is itself "one of the realities of external Nature," to use Prof. Soddy's definitions (NATURE, October 5, p. 90). The science of man, as a biological phenomenon that changes the aspect of the inanimate world and interferes with most branches of living matter—as an organism the groups of which have a definite life-history of growth and decay of ability, sometimes called cycles of civilisation—or producing collective average mentality, which results in rapid expansion of ability combined with great destructiveness—in all these ways the science of man appears to stand, like geology or astronomy, apart from all introspection. The purely scientific study by comparison of these phenomena in mass-action, apart from individual movement, is as scientific as the study of mass-action of matter, physical and chemical, apart from tracing the movement of single atoms. The understanding of this seems to be academically needed if we are to escape from British narrowness, and see the world whole. F.R.S.; F.B.A.

### Pre-Boulder Clay Man.

It will no doubt be remembered that at the time of the discovery in 1911 of a human skeleton in a sand pit in the occupation of Messrs. A. Bolton and Co., Ltd. (late Bolton and Laughlin), of Henley Road, Ipswich, it was held by some geologists and by myself that the remains occurred beneath an undisturbed stratum of weathered chalky boulder clay. Since this discovery I have been enabled to investigate extensively the small valley adjoining the sand pit in which the human skeleton was found, and to conduct excavations in the immediate vicinity of the spot where the bones occurred.

These investigations have shown that at about the level at which the skeleton rested the scanty remains of a "floor" are present, and that the few associated flint implements appear to be the same as others found on an old occupation-level in the adjacent valley. This occupation-level is in all probability referable to the early Aurignac period, and it appears that the person whose remains were discovered was buried in this old land surface. The material which *has since* covered the ancient "floor" may be regarded as a sludge, formed largely of re-made boulder clay, and its deposition was probably associated with a period of low temperature occurring in post-chalky boulder clay times.

*It* appears, then, that the human skeleton found is referable to a late Palæolithic epoch, and cannot *claim a pre-*chalky boulder clay antiquity. I wish to take this opportunity to state that those who opposed my contention as to the great age of these remains were in the right, while the views held by me regarding them have been shown to be erroneous.

J. REID MOIR.

12 St. Edmund's Road, Ipswich.

### Variable Stars.

THERE are good reasons for believing that when a molten sun has sufficiently cooled down to allow of the formation of a solid surface, the solid surface rapidly cools. We may, therefore, regard a cooling sun as passing through three stages: (1) a stage in which the light emitted is very intense and regular; (2) a stage in which the surface from time to time solidifies and breaks up again; in this condition the emission of light would be very variable; (3) a stage in which the crust had become so firm as to be practically permanent, little, if any, light being emitted.

The conditions obtaining during the second stage are supposed to be of comparatively short duration. May not some of the irregularly variable stars be in stage 2? If such were the case we should only expect a small proportion of the stars to show this variability; for there would be only a small proportion of them in stage 2.

R. M. DEELEY.

Abbeyfield, Salisbury Avenue, Harpenden, October 2.

[This question is dealt with in the Hill Observatory Bulletin, vol. i., No. 2, p. 4.—Editor, NATURE.]

### Scarcity of Wasps.

IT would be interesting to know whether the scarcity of wasps which is so marked in this district is of wasps. Also, while at Bordon (Hants.) for three weeks in August I saw only one wasp.

Are there general causes to account for the scarcity, such as the cold spring, or disease, or is there a cycle of fecundity and scarcity? Possibly some readers of NATURE have observed and remarked the absence of wasps this season in other parts of the country, and may be able to forecast the probable effect on insect pests next summer.

H. V. DAVIS.

"Noddfa," Wistaston, Crewe, October 3.

## *CAPT. KEITH LUCAS, F.R.S.*

ON Thursday last, October 5, Capt. Keith Lucas lost his life in a flying accident. In his short span of life—he was but thirty-seven—he had become the leading authority on the phenomena of excitation in nerve and muscle. He had gone through several phases. Coming up from Rugby, he obtained a minor scholarship in classics at Trinity College, Cambridge, and entered the college in 1897. He passed to natural science studies, and took a first class in the Natural Sciences Tripos. Soon after this he made a bathymetrical survey of a New Zealand lake. He then began research in physiology, was elected a fellow of Trinity in 1904, and a little later was appointed lecturer of the college and demonstrator of physiology in the University. The line of research he had chosen led to the development of his inherited faculty of mechanical design, and each additional step of his work was marked by the invention of a new instrument or by some striking improvement in instrumental methods necessary for the successful investigation of the problem. His exceptional mechanical ability found further scope when he became one of the scientific directors of the Cambridge Instrument Company.

On the outbreak of war he gave up work at Cambridge and undertook research at the Royal Aircraft Factory. His success in modifying the magnetic compass for use in the peculiar conditions of aircraft flight has been specially noted in the recently published report of the Advisory Committee for Aeronautics. The committee pointed out how greatly flyers are indebted to Dr. Lucas. His subsequent investigations afford an instance of his thoroughness and devotion to the work in hand. He acquired, as an accessory matter, a personal knowledge of the conditions of flight, and obtained a pilot's certificate. It was while engaged in this investigation that the accident happened which cost him his life.

Much as Keith Lucas had achieved in physiology, it is certain that, had he lived, he would have done much more. He conceived early the whole scheme of investigation necessary to settle his particular problem, and he followed it up step by step with unsurpassed logical method. So far as it can be said in science that the determination of a special problem depends on one man, it

## SIR AUREL STEIN'S THIRD JOURNEY IN CENTRAL ASIA.

SIR AUREL STEIN publishes, in the August and September issues of the *Geographical Journal*, an account of his third journey in Central Asia.

Starting from Srinagar, in Kashmir, in July, 1913, the first point of interest reached was the Darel Valley, where, at his new capital, Gumarekot, Raja Pakhtun-wali, son of Mir Wali, the murderer of Hayward the explorer, has succeeded in building up a new kingdom, the last, perhaps, which India has seen founded on the old adventurous lines. The fine glacier scenery of this region is illustrated by the view of the Chillinji Glacier (Fig. 1). In this valley of Darel the explorer succeeded in identifying, at Poguch, the site of

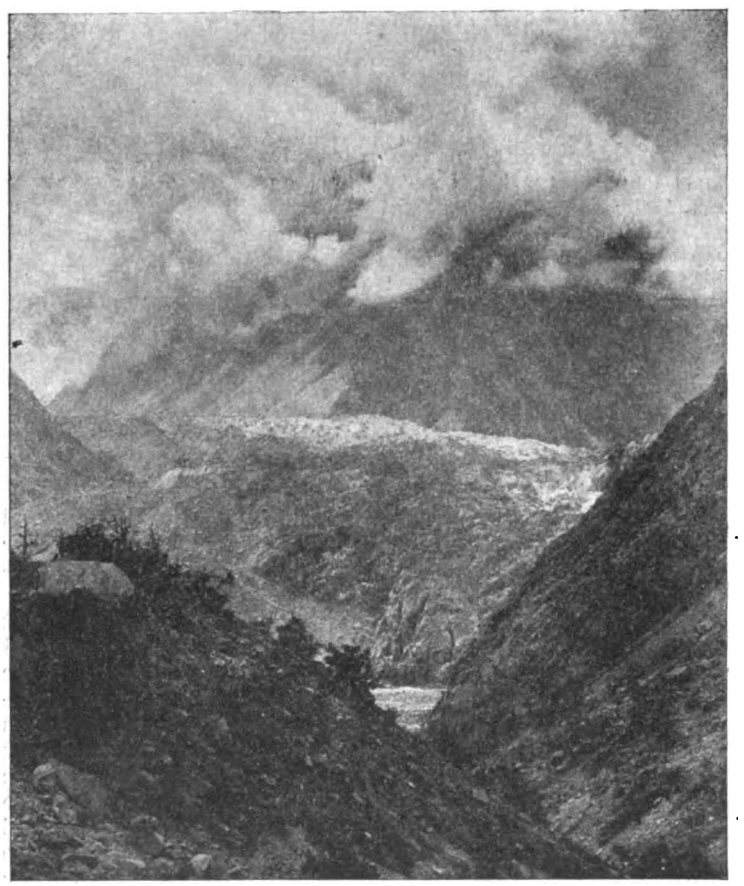

FIG. 1.—Lowes: portion of Chillinji Glacier, seen from west across Ashkuman River. From the *Geographical Journal*.

ground the traveller pushed on through the Yasin Valley to the Darkot Pass, the scene of the remarkable exploit by which a Chinese force, dispatched in A.D. 747 from Kashgar against the Tibetans, succeeded in effecting an entry into Yasin and Gilgit.

By the beginning of September the party reached the main head of the Hunza Valley, and marched thence to Tashkurghan and Kashgar, where, as usual, Sir G. Macartney, the British Consul-General, supplied liberal aid to the expedition. Since Sir Aurel Stein's last visit, owing to the Chinese revolution of 1911, the political situation had changed for the worse. Mandarins had been assassinated, and local revolts had resulted in a general weakening of Chinese authority. From Kashgar the goal was the region round the dried-up Lop-nor, in the extreme east of the Tarim Basin. Beyond Mural-Bashi, Stein reached the most forbidding region he had hitherto encountered in Taklamakan, and after meeting great difficulties he returned to his old station, Khotan. In this region many interesting discoveries were made. He succeeded in fixing the site of Hsuan-tsang's Pi-mo, the Pein of Marco Polo, at a Buddhist shrine near Domoku, and a large number of tablets inscribed in the Kharoshthi character, and dating from the first century of our era, was found.

Passing Charchan on New Year's Eve, 1914, he found that a band of so-called "gamblers," or vagrant outlaws, had overthrown Chinese authority. At Miran paintings of great interest, almost Hellenistic in style, were unearthed. Later on the ancient Chinese road into the Tarim Basin was identified, and further finds of decorated silk fabrics will contribute to the solution of the problem of origin in the designs discovered in an earlier journey near Tun-huang, usually attributed to Persian art of the Sassanian period. Equally interesting were the desiccated corpses of the old chief and his family, with their well-preserved arms and dresses. The illustration (Fig. 2) of an ancient fort near Lou-Lan gives a good idea of the sites which came under investigation.

The first portion of the narrative leaves the ex-

Digitized by Google

great barren hill region usually designated the Pei-shan Gobi. The site known as that of "The Thousand Buddhas," from which a large mass of material was collected in an earlier tour, in spite of an ill-considered seizure of manuscripts by the Chinese Government, was found capable of providing large additional hoards; while the survey of the ruins of Khara-Khoto established the identity of the site with Marco Polo's "city of Etzina." At the north foot of the T'ien-shan range he traced the original route through which all the historical migrations westward — Indo-Scythians, Huns, and Turks — must have passed. In May, 1915, the traveller returned to Kashgar, and it might have been supposed that the wayworn party would have been satisfied to return and convey the important collections of new material to India. But the indefatigable leader determined to take the opportunity of crossing the Pamirs to study the historical geography of that region. Here one of the most remarkable features of the landscape was the splendid glacier peaks of Muz-tagh, seen from the watershed, about 11,000 ft. high, on the Tars-agar Pass (Fig. 3). It is satisfactory to record that Sir Aurel Stein speaks in high terms of the results of the Russian Topographical Survey of the Pamirs, which had been in progress for some years before the outbreak of the war. At last his desire to visit Lake Victoria or Zor-Kol was satisfied, and thence he passed through Wakhan to Samarkand, and thence into Seistan, where, at Koh-i-Khwaja, he was lucky enough to discover the remains of a Buddhist sanctuary, the first ever traced on Iranian soil. Finally, passing through Baluchistan, he reached the Indian railway system at Nushki, by which he arrived at

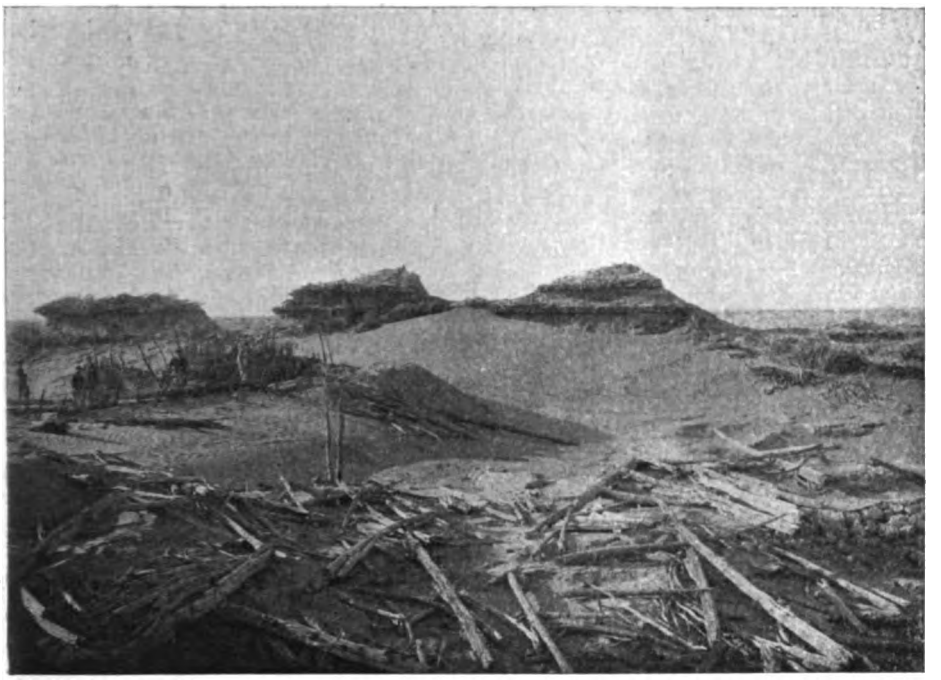

FIG. 2.—Interior of Ancient Fort with wind-breached portion o. Rampart, south-west of Lou-Lan site. From the *Geographical Journal.*

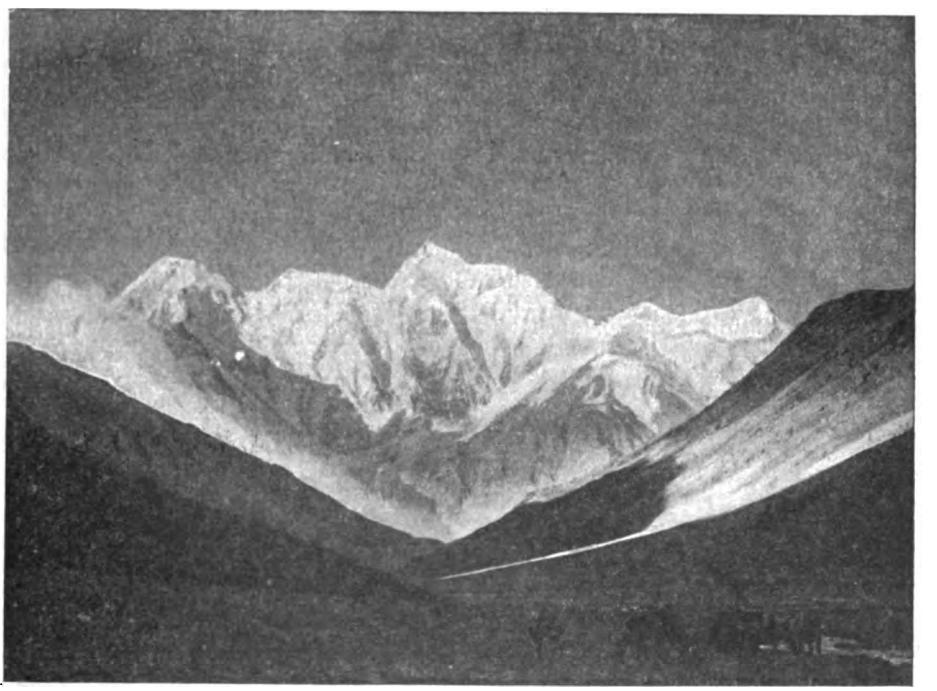

FIG. 3.—Glacier peaks of "Muz-tagh" above Muk-su, seen from watershed (about 11,000 ft.) on Tars-agar Pass. From the *Geographical Journal.*

Digitized by Google

Delhi to report the result of his journey to Lord Hardinge.

We cannot discuss the many interesting results of this remarkable journey. In the Pei-shan Sir Aurel Stein remarks that inscribed slips of wood, thrown out of ancient office-rooms, were often found in refuse-heaps, covered only by a few inches of gravel or *débris*, their preservation in such condition presupposing a remarkable dryness of climate during the last two thousand years. On the other hand, he points out that the final abandonment of the Khara-Khoto settlement was brought about by difficulties of irrigation, and "it was not possible to determine by conclusive evidence whether this failure of irrigation had been the result of desiccation in the Etsin-gol delta, or had been caused by some change in the river-course at canal-head, with which the settlement for some reason was unable to cope. But there seemed to me good reason to believe that the water-supply now reaching the delta during a few summer months would no longer suffice to assure adequate irrigation for the once cultivated area." Obviously the problem of the changes of climate during the historical period will need much further investigation before it can be finally solved, and in the present fragmentary state of our information the question should not be treated in a spirit of confident dogmatism.

It has been arranged that the Indian Government, which liberally contributed to the expenses of the journey, shall receive a considerable portion of the finds, which will be deposited in the new Museum of Indian Art and Ethnography which has been planned at Delhi. We are now so accustomed to the periodical reports of Sir Aurel Stein's explorations that we may fail to appreciate the remarkable courage, tenacity, and executive ability which he has shown in opening up a new region and in reconstructing a hitherto unknown chapter in the history of man.

## NOTES.

MR. RUNCIMAN announced in the House of Commons on Tuesday that he had decided to combine the existing Commercial Intelligence Branch of the Board of Trade and the Exhibitions Branch into a new and enlarged Commercial Intelligence Department. The reorganisation of the department is now proceeding.

A ROYAL Commission has been appointed "to inquire into the supply of wheat and flour in the United Kingdom; to purchase, sell, and control the delivery of wheat and flour on behalf of his Majesty's Government; and generally to take such steps as may seem desirable for maintaining the supply." The names of the members of the Commission are:—The Earl of Crawford (chairman), Alan Garratt Anderson (vice-chairman), Sir Henry Rew, K.C.B., Sir George Saltmarsh, H. W. Patrick, Hugh Rathbone, Oswald Robinson, J. F. Beale, and T. B. Royden. Communications intended for the Commission should be addressed to the secretary at Trafalgar House, W.C.

THE Harveian oration of the Royal College of Physicians of London will be delivered on Wednesday, October 18, by Sir Thomas Barlow.

THE Thomas Hawksley lecture of the Institution of Mechanical Engineers will be delivered by Mr. H. E. Jones on Friday, November 3, upon the subject of "The Gas Engineer of the Last Century."

WE learn from the *Times* that Prof. W. von Waldeyer, professor of anatomy in the University of Berlin, has been raised to hereditary nobility on the occasion of his sixtieth birthday.

THE death is announced, at seventy-seven years of age, of Mr. Herbert Jones, known by his work in archæology, particularly with reference to the Roman occupation of Britain, and investigations relating to it at Silchester, Carlisle, Roxeter, and Greenwich.

DR. LE ROY C. COOLEY has died at his home at Poughkeepsie, N.Y., at the age of eighty-three. He was professor of physical science at the N.Y. State Normal College from 1860 to 1874. In the latter year he became professor of physics and chemistry at Vassar College. He held that post until 1894, when he was appointed to the chair of physics in the same institution. He retired in 1907. He was the author of several text-books of physics and chemistry. In 1899 he was elected president of the N.Y. State Science Teachers' Association.

THE death is announced, in his fifty-seventh year, of Dr. C. S. Prosser, head of the department of geology in the Ohio State University, with which he had been connected since 1899. He had previously occupied the chair of natural history at Washburn College, Topeka, Kansas, and of geology at Union College, N.Y. He was an assistant-geologist of the U.S. Geological Survey, and of the State Geological Surveys of Kansas, New York, Ohio, and Maryland. In addition to many official reports, he had published works on the stratigraphic geology and palæontology of Pennsylvania, New York, Kansas, Nebraska, Maryland, and Ohio, the Devonian of New York, Pennsylvania, and Maryland, and the Permian of Nebraska, Kansas, and Oklahoma.

WE regret to note in *Engineering* for October 6 the death, on October 1, in his seventy-sixth year, of Sir W. Theodore Doxford, at his residence, Grindon Hall, Sunderland. As a shipbuilder Sir Theodore greatly assisted in the development and improvement of cargo-carrying steamers. In 1895 the output of the works on the Wear with which his name is associated exceeded that of any other shipbuilding establishment in the country. Sir Theodore became a member of the council of the Institution of Naval Architects in 1896, and was president of the North-East Coast Institution of Engineers and Shipbuilders in 1886-87. He took an active part in the public life of the district in which his works were located, and was a Deputy-Lieutenant of the county of Durham.

MR. J. ACKWORTH PLOMMER has presented to the Geological Department of the British Museum an unusually fine portion of a Hippurite from the Chalk of Boughton-under-Blean, near Faversham, Kent. The specimen is part of the conical valve of the shell, which must have measured from 2 to 3 ft. in length, with a maximum diameter of about 8 in. The shell-substance is more than 2 in. in thickness, and of the usual open texture. The fossil seems to belong to a species, *Radiolites mortoni*, which is already known by fragments from the English Chalk, and by finer specimens from the Cambridge Greensand. The rarity of Hippurites in the Chalk is curious considering their immense abundance in the limestones of corresponding age in central and southern Europe, and in certain

Digitized by Google

regions of Asia, where they form the main part of some mountains.

WHEN the Gilbert Club was inaugurated in 1889, it had nearly one hundred members. The president was Lord Kelvin, and the secretaries were Mr. Conrad W. Cooke, Prof. R. Meldola, and Prof. S. P. Thompson, all of whom, except Mr. Cooke, have since died. The first object of the club was to produce and issue an English translation of Gilbert's "De Magnete" in the manner of the folio of 1600. This was done, but no general meeting has been held since the club was inaugurated, and as the principal founder, Prof. Thompson, has passed away, it is proposed to wind up the affairs of the club. A general meeting will be held, therefore, in the rooms of the Royal Society of Arts on Wednesday, October 18, at 3.30 o'clock p.m., the Right Hon. Lord Moulton in the chair, for this purpose. Proposals will be made as to the disposal of the property of the club, consisting of the remaining copies of the book, as well as of such funds as are in the hands of the hon. treasurer, and matters will be brought forward of considerable interest to all who wish to perpetuate the memory of William Gilbert of Colchester.

THE death of Dr. Joseph Anderson, of Edinburgh, at the ripe age of eighty-four, removes a notable personality from the ranks of scientific workers. Born in 1832, he originally intended to devote himself to a scholastic career. After several years of teaching, three of which (1856–59) were spent in Constantinople, he turned to journalism instead, becoming editor of an important provincial newspaper in the extreme north of Scotland. It was during his nine years of residence at Wick that he found his true vocation. Caithness is singularly rich in prehistoric monuments, and Anderson's acute intelligence was at once attracted by the difficult problems which these present. He realised from the outset that the only hope of a solution lay in the rigid application of the methods of science. He therefore set himself to ascertain the precise facts, resolutely refusing to theorise unless and until a sufficient basis for induction had been securely established. His earliest results were so full of promise and were set forth in so lucid and incisive a style that, on a vacancy occurring in 1869, he received a unanimous invitation to accept the keepership of the National Museum of Antiquities in Edinburgh, and with it the assistant-secretaryship of the Society of Antiquaries of Scotland. These posts he held until 1913, when he retired with a Civil List pension. It is not too much to say that in the interval he revolutionised the whole study of Scottish archæology, his chief publications being his five series of Rhind lectures, which stamp him indubitably as a master of the science of research and of the art of clear exposition.

SIR ROBERT HUDSON, chairman of the Joint Finance Committee of the British Red Cross Society and the Order of St. John (83 Pall Mall), publishes in the *Times* of October 10 the following letter received by him from "A Past President of the Chemical Society" and "A Past President of the Society of Chemical Industry":—"An industrial body in the United States of America recently requested our scientific advice. We felt bound to reply that all extraneous work not desired by the State could only be undertaken on behalf of the British Red Cross Society, to which any honorarium must be directly transmitted. The corporation having responded most handsomely to our terms, we gladly hand over cheques each for 1000 guineas, forwarded under the condition above specified. The bounds of the scientific profession are very extensive, and many individuals are receiving large pecuniary benefits accruing, directly or indirectly, out of applied science. We earnestly hope that many colleagues will come forward and help on the beneficent work of the British Red Cross Society." Sir Robert Hudson expresses the hope that the fine example thus set by his two correspondents will commend itself to others; and we are sure that no objects make a stronger appeal to the scientific world than those with which he is associated. Very few men of science, however, are receiving such handsome fees as those which have just been forwarded to him, and most of them are engaged in national work of one kind or another without receiving any payment for their services. The appeal should be, therefore, not so much to scientific workers as to manufacturers and others who are benefiting by expert knowledge, often given gratuitously.

IN the June issue of the Journal of the Royal Society of Antiquaries of Ireland the address delivered by the president, Mr. T. J. Westropp, on "The Progress of Irish Archæology" is published. The society was founded in Kilkenny in 1849, and since then has held a high record for a long series of valuable papers published in its Proceedings. It was said when the society migrated from Kilkenny to Dublin that archæology in Ireland sprang from the novels of Sir Walter Scott or from Macpherson's "Ossian." There is some truth in this statement. The president's account of the early Irish antiquaries, among whom portraits of W. Mollineaux, C. O'Connor, C. Vallancey, and G. Petrie accompany his address, is lively and interesting. He speaks hopefully of the study of Irish antiquities, which, among its ablest students, exhibits a dislike for sweeping theories. But he remarks:—"In our country a bad theory—no matter how often refuted—never dies. Scientific antiquaries have too much to do to refute for the tenth or twelfth time these absurdities. We shall never be in a satisfactory position till in archæology, as in natural science, the man who attempts to revive an exploded error only slays his reputation and deceives no one but himself."

THE problem of the origin of what he called the Indo-Aryan type of Indian temples was never completely solved by James Fergusson, and later inquirers have done little to produce a solution. In the June issue of the Journal of the Bihar and Orissa Research Society Dr. D. B. Spooner, well known for his excavations at the site of Pataliputra, has in a great measure solved the difficulty. Beginning with the most primitive form of shrine, little more than a square box, he shows that the desire of the Indian architect was to produce a play of light and shade by advancing the central portion a little way, and then to repeat the process, so as to produce a lower structure decorated with three miniatures. At some stage of the local architectural history this threefold division seems to have come prominently into notice, and the architect conceived the idea of balancing this triplicity rhythmically by a corresponding threefold division of his tower in horizontal stories. This idea of the architectural rhythm is very ingeniously developed by Dr. Spooner, and his paper deserves the attention of architects. He closes by saying:—"The people of Tirhut are to be warmly congratulated on the possession of so complete a series of temples as they now possess, a series sufficient to illustrate the whole development of this important style, and a series including many shrines of special interest and beauty. Let us hope that they will do their best to safeguard their inheritance, and to maintain the temples we have seen in good condition."

THE "Terrapin" scale (*Eulecanium nigrofasciatum*) is the subject of Bulletin No. 351 of the U.S. Dept. of Agriculture, written by Mr. F. L. Simanton. This is a North American insect, closely allied to our European *E. persicae*, destructive to peach and plum, and feeding also on thirty other trees and shrubs. The females hibernate on the twigs, where, instead of laying eggs, they give birth to active young, which migrate to the leaves. Much damage is caused by the insects' honeydew secretion, which disfigures the fruit. The bulletin is well illustrated, and contains directions for remedial treatment, early spraying with a linseed oil and gasolene emulsion being especially recommended.

NOTES of much interest appear in the *Zoologist* for September on the mammalian fauna of North Cardiganshire. The author, Mr. Frank Wright, records the occurrence, during the last ten or twelve years, of a number of polecats of a very light colour, some individuals, furthermore, exceeding in size the more normally coloured animal. Both light- and dark-coloured individuals have been taken from the same pest. The pine-marten, he remarks, is now exceedingly rare, but a few apparently survive on the high plateau east of Tregaron. The foxes of the uplands also seem to differ from the type in the matter of coloration, being much greyer. But a specimen taken near the summit of Plinlimmon was quite black instead of white on the under parts.

MR. ZONIA BABER, in the *Scientific Monthly* for September, raises a timely protest against the wholesale slaughter of whales which is at present taking place throughout the seas of the world, and this without the slightest attempt at preventive legislation. The author, in his essay, "The Oceans: Our Future Pastures," holds that the time will come when men will have to depend upon the larger Cetacea for their meat supply, since the grazing of cattle will be impossible owing to the density of the population, which will cover the whole habitable globe. While we by no means agree with this view, we are at one with him that, for other and scarcely less cogent reasons, the present ruthless and wasteful exploitation of our whale fisheries constitutes a deplorable lack of foresight on the part of those engaged therein. The matter demanded international legislation long ago, and even now it is not too late, though, unless it come speedily, the Greenland and humped-back whales and the grey whale (*Rhachi anectes*) will have taken their places with Steller's sea-cow and the great auk—victims to man's greed.

IT is clear from the annual report of the British Museum (1915) that the Natural History Departments have been able to render useful aid to the military authorities in matters directly bearing on the war. In one case a leech, removed from the nose of a soldier invalided home from the Dardanelles, was sent to the museum from the military hospital in order that it might be identified and its habits described. A report on the matter was prepared by the keeper of the Zoological Department embodying useful advice and instructions, and this report was sent to the medical officers serving in the Mediterranean in order that the necessary precautions to avoid further infection might be taken. The Botanical Department was enabled to furnish the authorities of the Naval Air Service with valuable information in regard to wood suitable for airship construction. Further assistance was also given in regard to a fungus which was attacking the fabric of airships. Valuable work has also been done in regard to the supposed hibernation of the house-fly, and to the whaling industry in the Antarctic seas, which is carried on in the neighbourhood of South Georgia so thoroughly that some species are threatened with extinction.

THE best-known instances of luminosity in insects are to be found among the beetles; the various species of glow-worm and firefly belong to this order. But the same, or an analogous, phenomenon is occasionally observable in other insect groups, as, for example, in the "fungus gnats" and crickets. There are at least two well-authenticated records of luminosity in the larvæ of moths, and quite recently the Rev. J. Holroyde, vicar of Patcham, has reported to us an observation of luminous larvæ near Brighton. The species of these larvæ was not determined, but they appear to have been the caterpillars of a moth, probably a Noctuid. Boisduval, whose record is one of those above alluded to, believed that the luminescence in his larvæ was due to disease, and it has been suggested that decomposition due to bacterial infection is the cause of a similar appearance that has been described in other insects not usually luminous, as Chironomus (a kind of gnat) and the so-called "lantern flies" of South America. It is evident that the exceptional production of light in the cases just mentioned is very different in nature from the entirely normal illumination of the glow-worms and fireflies, though it may equally be due to the oxidation of some organic material.

THE excellent work in agricultural science which is being carried on at Moscow under the guidance of Prof. D. N. Prianichnikow is amply illustrated in the recently issued report (vol. x.) of the Agronomical Laboratory for the year 1914. As in past years, much attention has been devoted to the investigation of the merits as fertilisers of various natural phosphates and potash-bearing minerals, fully one-half of the papers included in the report having reference to these products. The assimilation and utilisation of ammonia by the plant have also received considerable attention. The experiments with phosphates have demonstrated the relatively high value of certain of the Russian phosphorite deposits, increases of crop as high as 60 to 70 per cent. of the highest obtained with superphosphate having been recorded in tests with cereal crops. This is in marked contrast to the results of earlier experiments recorded in previous reports, which indicated that, in general, phosphorites are almost valueless for cereal crops, though of appreciable value for leguminous crops.

USEFUL data as to the limits of tolerance of crop plants for sodium salts present in the soil are given by Messrs. Headley, Curtis, and Scofield in the latest issue of the *Journal of Agricultural Research* (vol. vi., p. 857). Experiments in Nevada have shown that the limit of tolerance is extremely variable, being influenced not only by such factors as kind of soil, salt, or crop, but the same crop plant shows marked differences in tolerance at different periods of its growth. So far as the amount of salt is concerned the limit of tolerance is dependent not so much upon the total quantity of the salt that may be present in the soil as upon the quantity that exists in the soil solution, and is recoverable from the soil by means of extraction with water. In pot experiments with soil from a tract of salt land in Nevada it was found that the proportion of recoverable salt which would reduce by one-half the growth of wheat seedlings was for sodium carbonate or bicarbonate 0·04 per cent. of the dry weight of the soil, for sodium chloride 0·16 per cent., and for sodium sulphate 0·35 per cent. The proportion of recoverable salt which prevented germination of wheat was for the carbonates 0·13 per cent., for the chloride 0·52 per cent., and for the sulphate 0·56 per cent.

THE investigation of the equations of motion of an aeroplane under the action of atmospheric disturbances such as gusts of wind is a problem to which attention was directed by Prof. Bryan in 1911 ("Stability in Aviation," pp. 178–79, problems 4, 13). An attempt to solve this problem has now been made by Prof. Edwin Bidwell Wilson (S. Doc., 268, Sixty-fourth Cong., 1st sess.). The method adopted in this case consists in treating the disturbed motion as a forced oscillation, the disturbance being expressed in the form of an exponential function of the time. Unfortunately, however, it is not possible to obtain a simple solution of the problem in a symbolic form, and what Prof. Wilson has been able to do is to obtain numerical results for a particular aeroplane of which the values of the stability-coefficients have been determined experimentally. It will thus be necessary to repeat the calculations every time a new aeroplane is built. Prof. Wilson has for no adequate reason departed from the standard notation in his choice of axes. The problem with which he is dealing is only the two-dimensional case of longitudinal disturbances, and it is the universal custom in treatises both on pure and applied mathematics to choose $x$ and $y$ as co-ordinates in all two-dimensional problems. The same practice was followed in the earliest stability investigations both in England and abroad, and the difference of notation is bound to cause confusion.

IN a paper which appears in the August number of the Science Reports of the University of Seddai Messrs. Honda and Okubo arrive at an expression for the force on one of the elementary magnets of a group arranged in a space-lattice due to the presence of the other magnets of the group. From this, on calculating the effect of an external field, they are able to obtain the magnetisation curve, and find it is identical with the well-known experimental curve. On varying the external field in the usual cyclic manner, the hysteresis loop is reproduced. It is then shown that the whole of the magnetic properties of magnetite can be reproduced on the theory that the elementary magnets constitute a cubic space-lattice, while those of pyrrhotine require a hexagonal lattice, as would be expected from its crystalline form. This molecular configuration for magnetite does not agree with that deduced by Bragg from the behaviour of the crystal towards X-rays. Finally, the authors show that the properties of ferromagnetic materials can be more completely and satisfactorily explained on the basis of the mutual action of elementary magnets than by the molecular field theory of Weiss.

A RECENT publication of the U.S. Coast and Geodetic Survey (Serial No. 23, Washington, 1916) gives the results obtained during 1913 and 1914 at the observatory near Tucson, Arizona. This observatory, which commenced operations in 1910, has a set of Eschenhagen magnetographs. The annual variation of temperature in the magnetograph chamber is about 13° C., but the diurnal range is only about 0·1°. Notwithstanding the favourable temperature conditions, the horizontal and vertical force magnetographs have given considerable trouble, large variations taking place in the scale values. The declination magnetograph has worked more satisfactorily, and as three absolute declination observations are taken weekly, the results for that element should be especially trustworthy. The Coast and Geodetic Survey has decided to refer all observations of horizontal force to the so-called "international standard" of the Carnegie Institution of Washington. This entails the application of a correction of $-23\gamma(1\gamma \equiv 1\times10^{-5}$ C.G.S. unit) to previously published values of horizontal force at Tucson, and of a corresponding correction to vertical force. Thus the mean annual values for earlier years printed in the present volume differ from those previously published. Opinions may differ as to whether this departure is not a little premature. Diurnal inequalities are given for the ten quietest days of each month and also for the five international quiet days. Mean monthly values are given for both these sets of days, as well as for all days. The all-day mean in horizontal force, on the average of the twenty-four months of the two years, is about $2{\cdot}6\gamma$ below the other two means. Seven folding plates reproduce the magnetograms showing the chief disturbances of the two years. The largest disturbance in both years occurred in April, but no disturbances were of outstanding magnitude. The observatory also possesses a Bosch-Omori seismograph recording N.-S. and E.-W. components of seismic motion. The earthquakes recorded are enumerated, and particulars are given of their principal features, but there is no information as to their epicentres. Much the largest disturbance recorded was that of March 30, 1914.

MANY engineers contend that the pressure over the teeth in modern high-speed gearing must be far from uniformly distributed. An interesting and new method for preventing any excessive concentration of the load on any part of the teeth is described in *Engineering* for October 6. The gearing was constructed by the General Electric Company of Schenectady, and used for coupling a high-speed steam turbine to a low-speed continuous-current generator. The wheels have double helical teeth, and the large wheel is built up of several comparatively thin discs, each separated from its neighbour by a small interval. The discs are bolted solidly together at their inner peripheries, but stand free from each other at their outer circumferences. Each disc has thus considerable axial flexibility, and if the load tends to be concentrated on any one of the discs, that disc bends axially, since the teeth are of the helical type. In this way the disc is relieved of the excess pressure, and a fairly uniform distribution of the load is secured. To enable the teeth to be cut on the rims of the discs, the discs are so made in the first instance as to be in contact also at the outer peripheries. The teeth can thus be milled without the discs springing, and after this operation is finished a narrow cut is made between the discs so as to obtain the required axial flexibility.

A SHILLING edition of Sir Ray Lankester's well-known and deservedly popular "Science from an Easy Chair" has been published by Messrs. Methuen and Co., Ltd. This is the ninth edition of the book, which was first published in April, 1910, and reviewed in our issue of July 14 of that year (vol. lxxxiv., p. 37)

A FRENCH translation of Prof. F. Soddy's monograph on the chemistry of the radio-elements, published in 1912, has been made by M. E. Philippi, and is issued by MM. Gauthier-Villars and Co., in Paris, under the title "La Chimie des Eléments Radioactifs." The price of the volume is 5 francs.

THE Wireless Press, Ltd., will shortly publish "The Measurement of Capacity and Inductance," by W. H. Nottage, illustrated, and a new and enlarged edition of "Elementary Principles of Wireless Telegraphy," by R. D. Bangay.

THE recently issued announcement list of the J. B. Lippincott Company includes the following new books and new editions:—"Shakespeare and Precious Stones," Dr. G. F. Kunz, illustrated: the work will treat of all the known references to precious stones in Shakespeare's works, with comments as to the origin of his material, the knowledge of the poet concerning

Digitized by Google

precious stones, and references as to where the precious stones of his time came from; "Rings," Dr. G. F. Kunz, illustrated; "The Art of Anæsthesia," Dr. P. J. Flagg, illustrated; and (in "Lippincott's Farm Manuals") "Productive Sheep Husbandry," Prof. W. C. Coffey, illustrated; "Productive Marketing of Farm Products," A. E. Cance, illustrated; "Productive Feeding of Farm Animals," Prof. F. W. Woll, new edition, illustrated; "Productive Soil Maintenance," C. E. Thorne, illustrated; "Animal Husbandry," Prof. C. W. Gay, illustrated; "Productive Grape Growing," Prof. B. S. Pickett, illustrated.

## OUR ASTRONOMICAL COLUMN.

FIREBALL OF OCTOBER 3.—Probably what was the most brilliant meteor that has appeared in the present year was seen on Tuesday, October 3, at 8.5 p.m. It passed over Devonshire, and, though the night was cloudy, it gave a very vivid illumination of the sky and landscape, and its apparition was witnessed by great numbers of persons in the S.W. counties of England.

The observations are, however, not very accurate or consistent one with another in consequence of there being very few, if any, stars visible at the time from which its path might be taken. The flight was vertical as observed at Bristol, and was similarly described at various stations in Devon and Cornwall, so that a radiant at or near the zenith is inferred. At Launceston, however, the course is stated to have been from E. to W., and the fireball burst when near the zenith. Mr. W. F. Denning has determined the real path from the data at hand, and places the probable radiant in the head of Cepheus. The height of the meteor was about 67 to 30 miles above a point of the earth's surface some 15 miles E.N.E. of Exeter. A few further observations from Dorset or Devon would be very valuable as affording a test of the accuracy of this result; any such observations should be sent to Mr. Denning, 44 Egerton Road, Bristol.

MERCURY VISIBLE BEFORE SUNRISE.—Mercury will be a morning star during the latter half of this month, and at its greatest western elongation at midnight following October 20. The planet will rise from a point a little S. of due E. at the following times:—

| | Mercury rises a.m. | Sun rises a.m. | Mercury precedes Sun h. m. |
|---|---|---|---|
| Oct. 15 | 4 51 | 6 26 | 1 35 |
| 17 | 4 48 | 6 29 | 1 41 |
| 19 | 4 46 | 6 32 | 1 46 |
| 21 | 4 46 | 6 36 | 1 50 |
| 23 | 4 50 | 6 39 | 1 49 |
| 25 | 4 58 | 6 42 | 1 44 |
| 27 | 5 8 | 6 46 | 1 38 |
| 29 | 5 17 | 6 49 | 1 32 |
| 31 | 5 27 | 6 53 | 1 26 |

The waning crescent of the moon will be in the same region of Mercury on the morning of October 25.

THE DISTRIBUTION OF B STARS.—An important memoir on the distances and distribution of the B (helium) stars has been published by Prof. Charlier (Nova Acta Reg. Soc. Sci., Upsala, series iv., vol. iv., No. 7). It contains all the details which led to the general conclusions previously announced (NATURE, vol. xcvii., p. 369). In a group of stars having the same luminosity, the distance ($r$) of each individual star can be deduced from the apparent magnitude ($m$) by the relation $r = R.10^{0.2\,m}$, where the parameter R is the distance for apparent magnitude 0.0. A first determination of R was based upon the proper motions and radial velocities of 156 stars brighter than 5th magnitude, for which the requisite data were available; its value is 4.76 siriometers (1 siriometer = a million times earth's distance from sun). The corresponding absolute magnitude, or apparent magnitude at a distance of one siriometer, is given by $M = -5 \log R$, and is equal to $-3.39$. It was next discovered that the fainter stars gave a somewhat smaller value of R, and the brighter stars a higher value. This anomaly was found to be due to the varying luminosities of the different sub-classes. Separate investigation of these showed, in the main, that types B1 and B2 have the greatest luminosity, R being 7.4 sir., whereas types B0, B3, B5 have a value of R = 3.3 sir. For each subclass the value of R appears to be independent of apparent magnitude. Having the value of R for each sub-class, the position in space of each star at once follows, and it results that the B stars form a well-defined cluster, gradually thinning out from the centre to a distance of 200 siriometers. The centre of the cluster, which Prof. Charlier supposes to be coincident with the centre of the stellar universe, is in R.A. 7.7h., declination $-55.6°$; it lies in a rich region in Carina, at a distance of 18.2 sir. from the sun. The cluster has an extension nearly three times as great in the plane of the Milky Way as in the direction at right angles, and the sun lies eccentrically with respect to it, at a distance of 4 sir. above the fundamental plane of the Milky Way. The mean density amounts to 0.0026 stars per cubic siriometer. A catalogue of the 804 known B stars is given, showing all the data relating to type, magnitude, distance, galactic co-ordinates, and so on. The distribution of the stars is further shown diagrammatically, and stereoscopic charts are in course of preparation. It is of interest to note further that the nearest B star is $\alpha$ Eridani, with a distance of only 4 sir. ($\pi = 0.0516''$), while the three stars in the belt of Orion come next, with a distance of 8 sir. So far as they go, direct determinations of parallaxes support the values of R used in the investigation.

THE SPECTROSCOPIC BINARY $\chi$ AURIGÆ.—An orbit for the spectroscopic binary $\chi$ Aurigæ (type B1) has been calculated by R. K. Young from eighty-eight single-prism spectrograms taken at Ottawa in the years 1913–16 (Journ. R.A.S. Canada, vol. x., p. 358). The period has the exceptional value, for an early type star, of $655.16 \pm 5.26$ days; the eccentricity is 0.171, and the orbital velocity 20.53 km./sec. The residuals from the simple elliptic orbit were examined for indications of the presence of a third body, but no secondary period was found; further investigation of this point, with high dispersion, is considered desirable. The calcium lines (H and K) have an amplitude of about half that shown by other lines of the spectrum. A useful summary is given of the different cases of anomalous behaviour of the calcium lines at present known, and Mr. Young considers that the phenomena are best explained on the supposition that there is a calcium cloud surrounding the binary, the absorption of this substance taking place at a much higher level than that of the other elements.

A NEW ASTRONOMICAL JOURNAL.—We have pleasure in directing attention to the publication in France of a new monthly periodical devoted to astronomy and meteorology. It bears the title *La Revue Verte*, and is edited by the Abbé Th. Moreux. The journal is intended especially for amateurs, and will include articles giving practical instruction in methods of observation, in addition to general astronomical news, and notes on celestial phenomena during each month. In the first number there is an article on sun-spots and meteorology by the editor, and the first of a series of articles on variable stars by Prof. Move. There is also a brief biography, with portrait, of M. Baillaud, director of the Paris Observatory. All communications are to be addressed to M. l'Abbé Th. Moreux, Observatoire de Bourges (Cher), France. The annual subscription is 6 francs in France, and 7 francs for other countries.

## GEOLOGICAL WORK IN THE UNITED STATES.

THE United States Geological Survey, under the directorship of G. Otis Smith, continues to discuss theoretical and practical problems from the most liberal point of view. T. Nelson Dale's account (Bulletin 589) of "Marble and Dolomite of Eastern Vermont" directs attention to a rose-coloured manganiferous calcite marble, "alternating in very small beds with equally small beds of fine-textured white dolomite." The author refers to his previous discussion of dolomite (Bull. 521), and suggests that the dolomite layers were precipitated inorganically, while the pink calcite layers received their manganese from organisms. Both the hard and soft parts of molluscs may contain appreciable percentages of manganese; but why should rose-coloured marbles be comparatively rare? The examples from Vermont lose their colour if used for external decoration.

In Monograph lxiii. F. Leverett and F. B. Taylor provide a detailed description of the "Pleistocene of Indiana and Michigan and the History of the Great Lakes." They conclude that the changes and deformations of shore-lines in this region may be due to crust-creep, as well as to alterations in the ice-burden, but (p. 333) that the land is at present stable. The long eskers, formed during glacier-retreat in channels bounded by the ice, are excellently illustrated in the maps (see, for example, plate viii.), and the elaborate nature of the survey may be judged from the folded sheet, plate vii., where the moraines of the peninsula between Lake Michigan and Lake Hudson, with the lacustrine clays deposited behind them, are shown over a region measuring 300 by 200 miles. The Michigan Geological Survey has furnished important data for this memoir.

Bulletin 600 is a popular guide to the geology and scenery of "The Glacier National Park," Montana. The Continental Divide runs through the park, among peaks carved out of stratified rocks, which are from 9000 to 10,000 ft. in height, and some 6000 ft. above the valley-floors. A few residual glaciers still linger in the cirques. The region was originally purchased from the reservation of the Blackfeet Indians, in order to encourage copper-mining. The mines having proved unprofitable, the beauty of the country was represented to Congress in 1910 (Fig. 1). A good map accompanies this bulletin; but those who become interested in the folding and overthrusting and subsequent dissection of the strata of the park may like to learn more about their geological age than that they "are very, very old."

In North Park, Colorado (Bull. 596), lenticular masses of coal of extraordinary thickness occur in Upper Cretaceous or early Cainozoic strata. These coals may be 20, 35, or even 53 ft. thick, and are referred by A. L. Beekly (p. 94) to local marsh-areas, unconnected with one another, which encouraged rapid accumulation of vegetable or other organic matter. North Park is unfortunately bounded by a ring of mountains, away from trade-routes, and the remarkable cleanness of the coal is likely to prove its chief recommendation.

W. W. Attwood (Prof. Paper 95B) records and illustrates a rather widely spread glacial boulder-clay of Eocene age in south-western Colorado. In a review of recorded "ice-ages," which excludes the evidences of mere valley-glaciers, the author finds no parallel with the Colorado instance, unless in the Eocene of North Italy. W. T. Lee (*ibid.*, 95C) provides a possible source of the Eocene ice-flow in a review of the "Relation of the Cretaceous Formations to the Rocky Mountains in Colorado and New Mexico." He urges that all the Cretaceous coal-seams of the region, from Dakota times onward, were deposited on the margins and sometimes towards the centre of a single gradually subsiding shallow basin, which (p. 57) reached from the Gulf of Mexico to the Arctic Ocean and from Utah to the Mississippi. The orogenic movement of Eocene times resuscitated the Rocky Mountain mass, which had been worn down and buried beneath these Cretaceous strata. Hence the beds which contain conglomerates derived from the newly raised mountains must all be regarded as of Cainozoic age. The folding experienced by the coal-bearing strata during the uplift is well seen in the illustrations from Utah in Bulletin 581E.

From Nevada (Prof. Paper 95A) W. B. Hicks

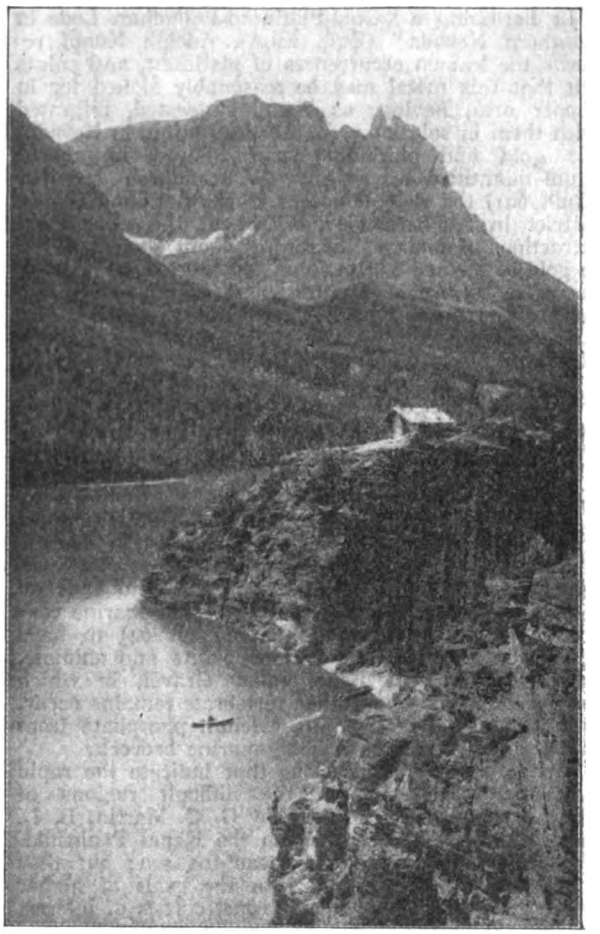

FIG. 1.—St. Mary Lake and Red Eagle Mountain, Glacier National Park, Montana.

draws interesting conclusions as to the apparent disappearance of potassium from the brines and saline deposits of the desert-basin regions. High percentages of potassium are obtained by boiling the muds of Columbus Marsh with water, and the author believes (p. 9) that these muds have withdrawn potash from percolating solutions, holding it in virtue of their colloids or in a weak chemical combination. Only a small proportion of the potash can be referred to extraction from the mud-forming minerals, and (p. 8) "the potash content of the muds is roughly constant without regard to the character of the material," *i.e.* whether this is sand or clay. The retention of potash by soil-particles has, of course, been discussed by

Digitized by Google

agricultural investigators, and it here receives a wide geological application. Hoyt S. Gale, in describing (Bull. 580L) the salines of Borax or Searles Lake, San Bernardino Co., California, touches on the same point, and regards the preservation of potassium chloride in the brine of this lake-area as quite exceptional. The analysis quoted on p. 294 of his paper, on which so much depends (see p. 311), seems to have gone far astray. Should we read 12·30 for the percentage of potassium chloride, in place of 1·50? The author's well-illustrated account of the salts crystallised in this desiccating region forms a convenient synopsis for students of mineralogy. Bull. 603 is of interest from the evidence given that the mineral oils north of Coalinga, California, originated in the decay of diatoms of Upper Cretaceous age.

In discussing a "Gold-Platinum-Palladium Lode in Southern Nevada" (Bull. 620A), Adolph Knopf reviews the known occurrences of platinum, and points out that this metal may be reasonably looked for in copper ores, having, as Kemp suggested, migrated with them in solution. At the Boss Mine, in Nevada, the gold and platinum occur alloyed in almost equal quantities by weight. W. Lindgren describes (Bull. 601) the rich gold ores of the national mining district in northern Nevada, where the exceptional attractions of quartz "averaging about $30,000 a ton in gold of a value of $10.60 an ounce" led, as recently as 1912, to armed alarums and excursions of the good old western type. A defensive searchlight has been kept playing on the entrance of the National Mine. Outside the National lode, the veins contain silver and antimony ores; but all the minerals are probably connected in depth, as products of ephemeral hot springs at a late stage in the eruption of Cainozoic (Miocene?) rhyolites.

G. C. Matson's description (Bull. 604) of "The Phosphate Deposits of Florida" is accompanied by a large coloured geological map of the State, on the scale of 1 : 1,000,000. The most interesting feature of this is the famous Florida East Coast Railroad, which steps from isle to isle of coral, and ends on the Pleistocene oolite of Key West. The marine concretionary phosphates are believed (p. 64) to have originated from the remains of plants and animals, while the fluviatile Bone Valley Gravel, in which teeth of Mastodon and other vertebrate remains occur, is held to have received its calcium phosphate from the detritus of the underlying marine bedrock.

Among several publications that indicate the rapid progress of surveying in the difficult regions of Alaska, we note Bulletin 587, by G. C. Martin, B. L. Johnson, and U. S. Grant, on the Kenai Peninsula. Cainozoic coal-seams occur near the sea; but they seem unlikely to compete with the coals of higher grade available on the Pacific coast. It is of interest to find (p. 52) a series of "green scoriaceous and ellipsoidal lavas" of Triassic age overlain by radiolarian cherts. Once more we see that a particular marine condition has brought about the formation of these two dissimilar rock-types, though the clear evidence of succession in this case prevents our ascribing the abundance of radiolarians to the emanation of silica from the lavas. The detailed work by C. W. Wright on Copper Mountain and Kasaan Peninsula (Prof. Paper 87) includes well-illustrated observations on contact-metamorphism. Some of the aplite veins (p. 81) contain as much as 9 per cent. of primary calcite, a mineral that has already taken its place as an original constituent of igneous rocks. S. R. Capps (*ibid.*, 95D) traces the volcanic ash layer of the Yukon basin to a "centre of dispersion," by no means central, north of Mount Logan. At this point the deposit is 300 ft. thick, fading away to a foot in about 150 miles to eastward. The layer is traceable over 140,000 square miles, and, from the thickness of peat above it on the White River, is ascribed to an eruption that took place on the north of the Mount St. Elias region about 1400 years ago. The report by A. H. Brooks, who superintends the surveying work in Alaska, on the mineral resources of the region in 1914 (Bulletin 622) includes an unfavourable judgment on some of the coals from the point of view of the Navy Department; the coal of the Matanuska field, however, is regarded as of excellent steaming quality, and the progress of gold-mining, the great industry of Alaska, may possibly open up this field.

W. B. Clark and M. W. Twitchell have written a monograph on "The Mesozoic and Cenozoic Echinodermata of the United States" (Monograph liv.), illustrated with 108 plates of drawings and direct photographs. While the genera are for the most part of world-wide occurrence, few of the familiar European species are found in American deposits. F. W. Clarke and W. C. Wheeler (Prof. Paper 90L) follow up their work on the composition of crinoid skeletons by an examination of the hard parts of other recent echinoderms. Magnesium carbonate is found in these also; the quantity is large in tropical forms as compared with those from cold waters, and may reach 14 per cent. The authors conclude that a rock formed from any kind of echinoderm "will have the composition of a moderately magnesian limestone." As previous workers have pointed out, the calcium carbonate of echinoderms is always in the calcite form.

Mineralogists and chemists will alike appreciate F. W. Clarke's essay on "The Constitution of the Natural Silicates" (Bull. 588), in which consideration is given to their alteration-products, as suggesting the structure of the molecule of the original mineral. The treatment of spodumene (p. 98) serves as an interesting example, and leads on to new interpretations of the pyroxenes and the amphiboles, which are worked out as mixtures of orthosilicates and trisilicates, while wollastonite and pectolite, which are easily decomposed by dilute acids, remain isolated as metasilicates. Whitman Cross (Prof. Paper 88) enlarges our imperfect knowledge of "The Lavas of Hawaii and their Relations," covering the Hawaian Islands as a whole. The mountain-chain of which these are the unsubmerged peaks extends for 1800 miles in a north-north-westerly direction. The rock-types offer no support to the suggestion of a distinctively Pacific group of igneous rocks, or a group produced under Pacific conditions, and the alkalic and calcic rocks of Rosenbusch occur in the islands (p. 86) as derivatives from a common source. The author doubts (p. 90) Daly's view that limestone has had an influence in promoting the occurrence of the types rich in alkalis. His visit to the islands in 1902 enables him to review his specimens as parts of some of the most striking volcanic landscapes in the world.

The twenty-third volume of the Iowa Geological Survey (1914) consists of O. P. Hay's monograph on "The Pleistocene Mammals of Iowa," the remains being found in interglacial beds. The Aftonian stage, following the first Glacial or Nebraskan stage, is especially the horizon of Mylodon, in North America, and of the last North American Camelidæ. The memoir is fully illustrated. R. S. Lull reviews (*American Journal of Science*, vol. xl., 1915, p. 319) "The Mammals and Horned Dinosaurs of the Lance Formation of Niobrara County, Wyoming," and shows that mammalian remains, including throughout the older multituberculate types, are found in almost all the beds that contain Ceratopsia. The tri-

Digitized by Google

tuberculate mammals occur, however, on the upper horizons, and may still have existing representatives. H. F. Osborn discusses the "Close of Jurassic and Opening of Cretaceous Time in North America" (Bull. Geol. Soc. America, vol. xxvi., 1915, p. 295), as an introduction to a symposium on the Morrison formation. This discussion has a special application in England to the Purbeck-Wealden question.

The Wisconsin Geological and Natural History Survey has reported on the north-western area of the State (Bulletin No. 45, Madison, 1915), where very little geological work had been done prior to the official entry of Mr. W. O. Hotchkiss and his assistants in 1913. Since the area lies in the Lake Superior iron district, great stress has been laid upon a continuous magnetic survey, the principles of which are set out in chapter iv. This illustrated essay of sixty pages will be of service to mining students in general. The ores are the well-known sedimentary masses of Huronian age, and the extent of the Huronian beds beneath the glacial drift has been largely determined by magnetic readings. Bush-covered ground and rivers, as indicated in the sympathetic pictures of geologists at work, have often hindered observation, and only the most careful organisation could have carried out the survey in so comparatively short a time. G. A. J. C.

## THE ZOOLOGICAL SURVEY OF INDIA.

WITH the sanction of the Secretary of State the Government of India has recently converted the professional staff and entire working machinery of the zoological section of the Indian Museum into an autonomous Government department, under the name and style of the Zoological Survey of India.

This conversion, if it were—as to superficial view it might appear—merely a change of name, could pass without comment in a momentous time like the present; but inasmuch as it effects a long-desired and fundamental improvement in the prospects and official status of zoology in India—a country where, private enterprise in the domain of natural science being undeveloped, no branch of science that lacks independent and avowed recognition in the highest official quarters can hope to expand to its full extent—it deserves some notice.

In times not very long past the zoological section of the Indian Museum was administered by trustees, on the model of the British Museum, an arrangement ill-suited to a polity where, outside official circles, trustees with the necessary academic experience are not easy to find. One of the most unsatisfactory results of this system was that, although all ate of one salt and owned the Government as their father and mother, the zoological officers—irrespective of professional seniority or length of service—had always to be the official subordinates of their *confrères* in kindred scientific departments, who were constantly associated with the museum as trustees.

This anomaly was rectified by making the senior zoological officer eligible for the office of trustee, a resort to legal fiction which, although it placed zoology in proper official perspective, was calculated to offend tender consciences.

All such fictions are now obviated by bringing the whole zoological staff and its appurtenance into line with other scientific departments of the Government of India, and placing the senior representative of zoology on the same footing as the directors of the kindred scientific surveys—a position in which his opportunities of advocating and initiating research are much augmented and his responsibilities as an independent scientific adviser to Government are distinct and direct.

In notifying this auspicious change the Government expresses the hope that the establishment of a zoological survey will be of value to India; and when it is remembered—apart from all the economic reflections of the matter—that in territories like India more than 75 per cent. of the annual mortality is due either directly or proximately to noxious animals and animalcules, so that rural sanitation in such countries must rest in the first instance upon accurate and comprehensive zoological foundations, there seems every assurance that this hope will be justified.

Apart from these internal changes, which bring field-work from a precarious position in the rear into the very front rank of the duties of the staff, and transform the trustees from responsible guardians into authorised visitors of the collections, the zoological section of the museum as a going concern will not be altered in any way. Nor is any extra expenditure anticipated for the immediate future, since the available museum grant is ample for the intended purpose, and the collaboration of the Marine Survey Department and the close co-operation of the Forest and Agricultural Departments are assured.

Under the new *régime* the national zoological museum of India promises to be, like some other Indian official organisations, an institution of an exemplary kind.

## GENETIC STUDIES IN PLANTS.

IN a paper on "Growth and Variation in Maize" (*Zeitschr. f. indukt. Abstammungs- und Vererbungslehre*, xiv., 1915, Nos. 3–4), Drs. Raymond Pearl and F. M. Surface combine the statistical and individual methods of inquiry. "We have tried," they write, "by studying the growth of the individual to analyse the adult variation curve into its component elements." Height is the character chosen for investigation; the relative variability as observed throughout the season "shows a marked progressive diminution," and the authors believe that the maize plant grows "in a series of cycles." In a second part of the paper they discuss the relation of variation to growth, and from the distribution of small, medium, and large plants conclude that the manner of growth is dependent on Mendelian factors.

Maize is also the subject of a paper in the *Journ. Agric. Research* (vi., No. 12) by G. N. Collins, who deals with "correlated characters" in the species. Eleven characters were selected for study, and of fifty-five possible combinations twenty were found to show significant correlations; but in all but five these appear to be physiological rather than genetic, and in no instance is the coefficient higher than 0·5. The author fears, therefore, that the method of isolating types is inapplicable to maize, though desirable characters derived from different parents may be easily combined.

The "Suppression of Characters on Crossing," illustrated by experiments on species of wheat, is discussed in a paper by R. H. Biffen (*Journ. of Genetics*, v., No. 4). He finds that dominant features, such as greyness of chaff or redness of grain, may be suppressed, so that "recessives make their appearance in $F_2$ generations from crosses of parents showing dominant characters only." This may perhaps be due to the existence of more than one factor giving rise to apparently the same dominant character, and the consequent possibility that two factors determining the recessive may meet in some of the zygotes that give rise to the $F_2$ generation.

Dr. T. Tammes contributes a paper to the Proceedings (xviii., No. 7) of the Kon. Akad. v. Wetensch. Amsterdam "On the Mutual Effect of Genotypic Factors." She has experimented by crossing varieties of flax differing in colour (blue or white) and breadth

Digitized by Google

of the petals. The results are complicated, and not readily summarised, but they confirm a generalisation already established by work in hybridisation among both plants and animals; that "views on the presence and action of factors obtained by an investigation of one single crossing are liable to modification when one of the forms investigated is crossed with a third form. Hence it is necessary to cross the same form with more than one partner in order to arrive, step by step, at the truth."

## MATHEMATICS AND PHYSICS AT THE BRITISH ASSOCIATION.

THE first of the two organised discussions arranged for this section was on "Gravitation." The discussion followed immediately after Prof. Whitehead's presidential address, and it happened that the arrangement was appropriate, for the president's exposition of the logical texture of geometry had carried us far from the ordinary conceptions of space, and paved the way for the revolutionary ideas associated with the space-time world of Einstein and Minkowski. Mr. E. Cunningham, who opened the discussion, and Prof. A. S. Eddington, who followed, dealt with Einstein's recent work, which brings gravitation within the scope of the principle of relativity. If an observer is in a closed lift, it is well understood that an acceleration of the lift upwards is exactly equivalent to an increase of the force of gravity, so far as mechanical phenomena inside the lift are concerned. There would, however, be minute differences in the optical phenomena according to the ordinary theory; relatively to the accelerated lift the path of a ray of light would seem to be curved, whereas for the stationary lift it would be straight if the increased gravitational field makes no difference. Accordingly, the first suggestion towards a relativity theory which shall include gravitation is that the path of a ray of light must be bent by the gravitational field, just as it is apparently bent by an acceleration of the framework of reference. The curvature to be expected is extremely small—amounting to a change of direction of 1·7″ in the case of a star seen close to the sun's limb—and it has not been possible to prove or disprove the hypothesis directly. Meanwhile the theory has been elaborated and generalised by Einstein, who has at length been able to throw the laws of motion, of electrodynamics, and of gravitation into a form which makes the sequence of phenomena entirely independent of any particular framework of reference. The result has been to yield a very striking confirmation of the theory, for it is found to predict a motion of the perihelion of Mercury amounting to 43″ per century—just the amount of the hitherto unexplained discordance. The new theory removes what is probably the most celebrated of the few cases of failure of gravitational astronomy. The discussion afterwards turned to the experimental side. Dr. P. E. Shaw gave an account of his experiments which appear to indicate a change in the constant of gravitation with temperature, and Prof. R. A. Sampson urged that astronomical evidence is not capable of denying this possibility. Dr. W. G. Duffield read a report of the Committee on the Determination of Gravity at Sea, considering especially the difficulties attending the use of the aneroid method, and the possibility of improvements in future attempts.

A paper by Sir Ernest Rutherford on the "X-Ray Spectra of the Elements" [illegible] that there are ninety-two elements up to uranium. By finding the atomic number of lead it has now been possible to assign the whole series of radio-active products to their places in the scheme. Sir E. Rutherford further described the work done in America with the Coolidge tube, which provides a steady high voltage. It is found that the maximum frequency of the rays which can be obtained follows closely the quantum relation $Ve=h\nu$, the accuracy between 20,000 and 100,000 volts being one per cent. To excite the characteristic radiation of a substance a rather higher voltage is needed than that given by the quantum relation, as though it were necessary to expend some energy in disturbing an oscillator.

Prof. H. H. Turner read a paper on the "Measurement of Time," dealing with daylight saving and justifying the innovation from a scientific point of view. The paper elicited an interesting speech from Prof. J. Perry, who admitted that he had formerly rather thoughtlessly opposed the scheme, and urged the warning against being led by authority in science. Other members, however, professed themselves still unconverted.

Prof. T. H. Havelock gave a review of recent work on the "Propagation of a Signal in a Dispersive Medium." He described the approximate methods of calculation which have been used, showing the relation between the recent methods of contour integration and the older work of Hamilton and Kelvin. The precise nature of the "forerunner," or minute disturbance which travels through the medium in advance of the main signal, is a matter of special difficulty, and an exact solution for any particular cases that may prove tractable would be a great help towards progress.

The absence of several speakers who had been expected to take part rather detracted from a discussion on "Osmotic Pressure," opened by Prof. A. W. Porter. There were many other interesting papers, most of which we must pass unnoticed for want of space, but special mention may be made of Prof. J. C. McLennan's paper on "Ionisation Potential," continuing and extending the results communicated last year; also of Sir F. W. Dyson's "Mean Parallaxes of Stars of Different Magnitudes," which in the main confirm the well-known formulæ given by Kapteyn in 1901. At a separate meeting of the department of mathematics Prof. G. N. Watson gave a general survey of the recent developments of the theory of asymptotic series.

A new departure, which it is hoped may lead to important results, was the formation of a committee representing Sections A and E to consider the needs of geodetic research. This arose from the presentation of a report by Col. Close, Sir F. W. Dyson, and Col. Hills, prepared at the request of the Organising Committee of Section A. The report brought out clearly the lack of organisation and general neglect of higher geodesy in this country, and there was a unanimous feeling that steps should be taken towards the constitution of some committee or association responsible for stimulating this branch of science.

## THE BRITISH ASSOCIATION AT NEWCASTLE.

### SECTION D.

#### ZOOLOGY.

ABSTRACT OF THE OPENING ADDRESS BY PROF. E. W. MACBRIDE, M.A., D.Sc., F.R.S., PRESIDENT OF THE SECTION.

Digitized by Google

last twenty years by selective mating, but the study of the laws governing the development of the germ into the adult organism—in a word, of experimental embryology—might eventually throw a great deal of light on the laws of heredity.

After alluding to the work of His, who sketched out the programme of the new science, Prof. MacBride described the work of the first experimenters—Roux, Hertwig, and Driesch—in some detail. He pointed out that the results obtained by these zoologists led them to conclusions about the nature of development which were fundamentally opposed to one another; for Roux, having produced half-embryos by destroying one blastomere of the two-cell stage of the frog's egg, supported the principle of "specific organ-forming regions of the germ," whilst Driesch, having reared a perfect Echinoderm larva of diminished size from one of the first four blastomeres of an Echinus egg, asserted that "the fate of a cell was a function of its position in the embryo," and in this conclusion he was supported by Hertwig, who attempted to interpret Roux's results in a different manner. Even Roux admitted that although half-embryos were formed at first, if they survived they regenerated the missing parts; Roux accounted for his results by supposing that each region of the germ had its peculiar organ-forming substance, or "idioplasson," which conferred on it the power to develop into a definite organ; the regeneration of lost parts he attributed to a special substance, which he called "reserve-idioplasson," which came into play only when mutilation had occurred. Driesch assumed, on the other hand, the existence of a purposeful "entelechy," or "psychoid," inhabiting the living material, and even when, as in his experiments with Ctenophore eggs, he found that isolated blastomeres gave rise to partial larvæ, he did not conclude that definite organ-forming substances were localised in each of the first eight blastomeres; but rather that in these eggs the cytoplasm was so specialised or "stiffened" that the indwelling entelechy could not mould it to its will.

The definite proof of the existence of *organ-forming substances*—a proof which was regarded as one of the great advances made by experimental embryology—was brought by Crampton and by Wilson in their studies of the developing eggs of Mollusca. In the developing egg of Dentalium and of some other Mollusca the first cleavage appeared to divide the egg into three cells, but one of these cells was a mere protrusion devoid of a nucleus, termed the *first polar lobe*, which was reabsorbed before the next cleavage. At the next cleavage five cells were apparently produced, but again one of these was a transitory *second polar lobe*, which melted into one of the four blastomeres before the cleavage to form eight cells began. If the first polar lobe were cut off, the egg developed into a trochophore larva, which was devoid of the apical plate and apical tuft of cilia and also of mesoderm, and of the whole post-trochal region. If the second polar lobe were cut off, a trochophore larva was formed, provided with apical plate and apical tuft, but devoid, as before, of mesoderm and of post-trochal region. The conclusion was inevitable that the specific material for the apical plate and post-trochal region was contained in the first polar lobe, but that the second polar lobe only contained the necessary material for the post-trochal region.

Driesch's objections to this conclusion were founded on the difficulty of conceiving what an organ-forming substance could be like, it being very difficult to picture a substance the molecules of which had the power

liar phenomenon with one about which we thought we knew more. Driesch's entelechy was really an attempt to compare the forces which organise development with the purpose of an intelligent being who wanted to build a house, and, in principle, no fault could be found with it. The great difficulty about it was that this comparison does not help us to understand in the least a large number of phenomena which could be far better "explained" by the theory of organ-forming substances, even although we could not tell what these substances were like. In the development of the Ascidian, *Cynthia partita*, as described by Conklin, the cytoplasm was rendered slaty-blue by inclusions of yolk, and in its outermost zone were numerous particles of bright yellow pigment. Before fertilisation the large germinal vesicle burst, and its contents formed a cap of clear fluid at one pole of the egg. The spermatozoon entered at the opposite pole, and then the clear substance and the yellow pigment were drawn down to meet it, and eventually formed two concentric crescents round the lower pole of the egg. Subsequent development made it plain that the clear substance gave rise to the ectoderm, the slaty-blue cytoplasm to the endoderm, and the yellow material to the mesoderm of the Ascidian tadpole. If one of the first four cells of the segmenting egg were killed, the other three continued their development, and an imperfect embryo was produced; if this cell happened to be one of the two containing yellow substance, a tadpole was produced which had muscles only on one side of its tail. Clearly in this case the organ-forming substances were visible to the naked eye, since they were distinguishable in colour, and their segregation in different regions of the embryo was the real cause of the *differentiation of the germ-layers*. In this process the individual cell was not a unit of any importance; both notochord and nerve-cord arose from the same group of cells, termed by Conklin *chorda-neural cells*; but the cytoplasm of these cells consisted of clear and blue portions, and in the subsequent divisions the clear portions were added to the ectodermic neural plate, whilst the blue portions became the endodermic notochord.

Driesch explained phenomena like these by asserting that these substances were the *conditions*, not the *causes*, of the development of organs; but another experiment, due to Morgan, which had been repeated in the laboratory of the Imperial College of Science, appeared to dispose completely of the idea of there being an intelligent entelechy presiding over development. This experiment consisted in fastening frogs' eggs to a slide, with the black pole uppermost, and fertilising them in this position. When the eggs had divided into two another slide was laid on the top of them and clamped in this position; the whole preparation was then inverted and allowed to develop for five or six days in this position. At the conclusion of this period a double-headed, or double-tailed tadpole was produced. In this case nothing was added to the egg, but the dark substance, which was specifically lighter than the white substance which constituted the rest of the egg, had readjusted itself in each cell under the influence of gravity, in a similar manner to what it would have done in the whole egg if this had been inverted before division into two had taken place. Hence the condition of the formation of a frog embryo must be the *proper spatial relationship between two organ-forming substances*.

If we adopted the view that organ-forming substances were the all-important agents in development, it became of the utmost importance to learn more about

Digitized by Google

which produced the ectoderm and the other the internal organs. Boveri showed that if these eggs were fixed to a slide which was inserted in a centrifugal machine and a rapid rate of rotation maintained whilst the egg developed, some of them the axes of which happened to lie exactly in the radius of rotation divided into two equal cells, both of which formed internal organs, and neither of which behaved like the cell in the normal embryo, which produced ectoderm. The slightest obliquity of the egg axis to this radius caused the egg to undergo normal development. This experiment, which had been repeated by us in the Imperial College of Science, showed that some substance was present in greater quantity on the outer part of the egg, so that the upper of the first two cells received more of it than the other, and was thus determined to form ectoderm, but that when under stress of the centrifugal force the division plane separating the first two blastomeres took up an exactly radial position, so that this substance was equally distributed to both cells, neither developed into ectoderm.

The question where these substances were formed was of great importance. *A priori* considerations suggested that they must emanate from the chromatin of the nucleus, since the father was as potent in heredity as the mother, and his contribution to the zygote consisted merely of a mass of chromatin. This conclusion was confirmed both by observation and experiment. In the unripe egg of Cynthia, Schaxel had shown that streams of chromatin poured from the nucleus into the cytoplasm, and if the unripe egg of Ascaris was subjected to the most violent centrifugal force, so that it lost large portions of its substance, and was afterwards fertilised, it gave rise to a normal embryo of diminished size, showing that its cytoplasm was not yet organised as was that of the ripe egg, the different development of which under the stress of centrifugal force we have just described. The pressure experiments of Driesch and Hertwig, in which, by allowing eggs to develop in cramped positions, they disarranged the normal order of the nuclei, showed that the nuclei of the segmenting egg were alike, each possessing all the potentialities of the species, for these distorted eggs when relieved from pressure developed into normal embryos, although the nuclei had assumed abnormal positions, and it was the relative position of the *substances* produced by these nuclei, not of the nuclei themselves, which determined differentiation. Sometimes, as in Herbst's famous experiment of allowing Echinus eggs to develop in sea-water to which salts of lithium had been added, it was possible to inhibit the formation of one of these substances and produce an embryo consisting entirely, or almost entirely, of endoderm. The formation of these substances appeared to last for only a short period; after that, the nuclei appeared to be without formative influence on the cytoplasm, but in animals like Polyzoa and Ascidians which bud, this budding could be best explained as due to a renewed production of organ-forming substances by the nuclei. These substances were often not distributed to the formative tissues of the bud in the same manner as in the embryo, and hence the development of the bud often followed a different course from that initiated by the embryo. The "post-generation" of the missing half, observed by Roux in his half-tadpoles, and by Chun and Mortensen in their half-Ctenophore larvæ, could be explained in a similar way by postulating a renewed activity of the nuclei at the cut surface. Considerations of this kind were fatal to the conception of Weismann of the definite segregation gated at an early period of development would scarcely supply the needs of the first spawning season, and that the eggs needed for subsequent seasons were formed by the metamorphosis of ordinary peritoneal cells.

Next to the discovery of organ-forming substances perhaps the greatest discovery in experimental embryology was the influence which the primary organs exerted on each other's further development. The first discovery of this influence was due to Herbst, who showed that if the ocular peduncle of a shrimp were amputated, the animal was able to regenerate a new one, as was the case also if the other limbs were cut off; but that if the optic ganglion was also removed then an antenna-like organ was regenerated in place of an eye. From this experiment the conclusion was forced on us that in the normal development of the shrimp the ectoderm was caused to mould itself into the retinulæ and crystalline cones of the eye by some influence emanating from the optic ganglion. This influence must be some chemical substance emitted into the blood and comparable to the hormones, which we know to be emitted by organs like the thyroid gland, which so powerfully influence growth in man. Another instance of the same thing was afforded by the experiments of Lewis; this observer cut off the optic vesicle from the brain of a young tadpole, and pushed the amputated organ backwards under the skin to a new position; the wound healed up; no lens developed in the normal position, but a lens was developed from the skin situated over the optic vesicle. This experiment proved that no part of the skin was predestined to form the lens of the eye, but that any part could form the lens if acted on by the emanations from the optic vesicle beneath. A third instance was discovered from experiments in the Imperial College of Science in the rearing of the larvæ of the sea-urchin, *Echinus miliaris*. In normal development the rudiment of the water-vascular system or "hydrocœle" was formed from the cœlomic vesicle on the left side of the larva. Above it the ectoderm became invaginated so as to form the amniotic pit, from the floor of which were developed pointed spines and tube-feet, whilst beneath the hydrocœle a series of pockets grew out from the left posterior cœlomic vesicle which developed into Aristotle's lantern. On the right side of the larva two calcareous plates were developed bearing square-topped spines and pedicellariæ. Under the influence of certain stimuli the larva could be made to develop a second hydrocœle on its right side, and when this took place, from the octoderm of the right side and from the right posterior cœlomic vesicle respectively a right amniotic pit with spines and tube-feet and a right Aristotle's lantern were developed. In other circumstances the formation of a hydrocœle could be inhibited altogether, and then calcareous plates bearing spines were formed on both sides of the larva.

If the second or right hydrocœle was small, it failed to inhibit the formation of plates bearing spines and pedicellariæ proper to the right side, so that both hydrocœle and pedicellariæ could be present together on the same side. The only possible explanation of these facts was the view that any part of the ectoderm could form an amniotic pit, and either left or right cœlomic vesicles could form an Aristotle's lantern, if acted on by influences emanating from the hydrocœle, and that both sides of the larva were really alike in their constitution, and that in the total absence of a hydrocœle each produced calcareous plates with spines.

The discovery of the profound influence exercised by the growing tissues of the embryo on one another

Digitized by Google

the case, that the production of hormones was not at all confined to certain ductless glands, but was a much more widespread phenomenon, we could understand that if, through an alteration in external conditions, a change was induced in some tissue, its chemical emanations would be altered. If, further, these altered substances, circulating in the body fluids, were ultimately stored up in the germ-cells, then eventually as the germ developed the corresponding alteration would be produced in the tissues of the young animal, even before it was exposed to the changed environment.

Of course, the proof that such an influence of a changed environment on subsequent generations was possible must ultimately be found by experiment, and the inherent difficulty of such experiments was very great, but some suggestive work by Kammerer on the inheritance of colour in Salamanders seemed really to supply positive evidence in favour of the inheritance of environmental influence.

In conclusion, let us bear in mind that the hormone theory of the inheritance of acquired characters which a study of experimental embryology inclines us to regard with favour was in principle identical with the theory of "pangenesis" propounded by the founder of modern biology, Charles Darwin.

## *UNIVERSITY AND EDUCATIONAL INTELLIGENCE.*

LONDON.—A series of public lectures, under the general title of "The University and the Nation," will be delivered on Wednesdays, at 5.15 p.m., at King's College. The lectures will be as follows:—October 25, The Root Fault in the English Attitude to Education, Dr. Burrows, Principal of King's College; November 1, Science and Industry, Mr. James Swinburne; November 8, Science and the Training of the Citizen, Principal Griffiths; November 15, The Spiritual Appeal of the Humanities, Mr. A. C. Clutton-Brock; November 22, The Intellectual Groundwork of Politics, Dr. H. A. L. Fisher; November 29, Education—the Curse of Convention, Mr. Graham Wallas.

Dr. Marie Stopes will begin a course of six lectures and demonstrations on "The Bennettitales" on October 17, at 5 p.m., at University College. The course will be illustrated by lantern-slides and specimens, including microscopic sections of new species. Further particulars can be obtained from the secretary of University College.

Prof. J. A. Fleming will deliver a public lecture on "Long-Distance Telegraphy and Telephony," at University College, on Wednesday, October 18, at 5.30 p.m. This lecture is open to the public without fee or ticket.

OXFORD.—On October 7 the Vice-Chancellor (the Very Rev. T. B. Strong, dean of Christ Church), on entering upon his fourth year of office, delivered the customary address. After mentioning that about 10,500 members of the University were serving in the Army and Navy, and about 500 were in other Government employment, he spoke of the distinctions gained by them in the present war, including 9 V.C.'s, 120 D.S.O.'s, and 700 mentions in despatches. [illegible] School of Chemistry was an attempt by the University to put the study of that science on a more satisfactory footing. But it should not be forgotten that the majority of Oxford men would be engaged in the work of administration, for which the knowledge of men was essential.

The University has received with much regret the news of the death of Mr. Horace Hart, who for more than thirty years conducted, as controller, the business of the University Press with marked ability and success.

A MEETING of the Association of Technical Institutions will be held in London on Friday and Saturday, October 20–21. For some time it has been felt that the members of the association should meet together to consider educational questions having special bearing on the work of technical schools and colleges. The governors of the Imperial College of Science and Technology, South Kensington, have placed rooms in the college at the disposal of the association for the purposes of the conference. Sir Alfred Keogh, K.C.B., president of the association, will preside over the meeting. The Right Hon. A. H. Dyke Acland, chairman of the Executive Committee of the Governors of the Imperial College, will welcome the delegates to the college at their first session. On the Friday morning Lord Haldane will deliver an address on "Education after the War, with Special Reference to Technical Instruction." This will be followed by a paper by Sir Trevor Dawson (of Vickers, Sons and Maxim) on "Education after the War, with Special Reference to Engineering Instruction." The afternoon of Friday will be devoted to a discussion of the address and paper. On Saturday, October 21, Major Mitchell, director of the Regent Street Polytechnic, London, will read a paper on "What Can be Done to Train Disabled Sailors and Soldiers in Technical Institutions," to be followed by a discussion.

IN presenting the Education Estimates to the House of Commons on July 18, the President of the Board of Education said that in addition to three committees of experts to investigate different educational questions, a fourth committee was to be appointed which would be a Reviewing Committee. The three expert committees are dealing respectively with the education and care of young persons after the war, and the position of science and modern languages in our educational system. Mr. Bonar Law stated, in the House of Commons on October 10, that the Reviewing Committee, which will be a sub-committee of the Prime Minister's Reconstruction Committee, has for its terms of reference:—"To consider the system of education as a whole; to review and formulate from that point of view proposals for developing it, particularly in directions indicated as desirable or necessary by experience gained during the war, and with special reference to:—(*a*) Proposals prepared before the war for the development of the national system of education; (*b*) the memoranda already submitted by the Education Departments for the consideration of the Reconstruction Committee; (*c*) any proposals submitted hereafter from the departments, or from special committees, or from other responsible organisations;

Trade Journalists, and the British Association of Trade and Technical Journalists paid a visit to these cities on October 8–10. At Leeds University the visitors were received by the Vice-Chancellor, Dr. M. E. Sadler, who gave an inspiring address descriptive of the University's work and its close associations with local industries. The departments visited included those dealing with organic and tinctorial chemistry, leather manufacture, textile work, gas and fuel. The members of the party were then the guests of the Leeds Luncheon Club, after which the Leeds Army Clothing Depôt, the works of Messrs. Albrecht and Albrecht (khaki garment manufacturers), and the Cardigan Boot Factory were inspected, these industries being selected in view of their close connection with the work of the University. Finally, the visitors were the guests of the Lord Mayor for tea. At Sheffield the Vice-Chancellor, Dr. H. A. L. Fisher, also addressed the visitors, who were conducted over the chemical and medical departments, while Prof. Ripper gave an account of the many special interesting researches undertaken on metallurgy and the testing of steel. The factories visited included the armament works of Messrs. John Brown and Co., where the party was invited to lunch by the Master Cutler, and the shell factory of Messrs. Thos. Firth and Sons. A feature in the arrangements at both cities was the co-operation of journalists representing the local papers, and the visits furnish an interesting illustration of the growing desire for closer relations between the universities and the Press. The visitors were much struck by the pride taken by Leeds and Sheffield in their universities, and the general recognition among local manufacturers of the value of the work that is being done there.

# THE "GALVANOSET" No. 1

A device for utilising the main supply of electricity, continuous or alternating, of any voltage, for the *immediate* production of low voltage currents from 0·5 to 100 volts such as are required for

**LABORATORY EXPERIMENTS.**

This apparatus has been largely employed by the medical profession for producing the currents that are required for passing through the human body, for which purpose accumulators and dry cells have been hitherto employed.

The apparatus comprises a vessel of water, two fixed electrodes, and two movable electrodes. The main current is connected through two lamp resistances to the movable electrodes, and the circuit of utilisation is connected to the two terminals shown at right and left of the vulcanite top of the vessel.

When the four electrodes are at right angles, *i.e.* at equal distances apart, the potential at the utilisation terminals is zero; when moved a degree from this position, a potential is at once obtained varying in intensity with the amount of displacement. The polarity of the supply can be readily reversed by moving the pointer in the opposite direction. The complete apparatus weighs 7 lb. only. The price of **£8 8 0** includes a moving coil milliammeter with shunt winding; if this is not required, the price is only **£6 6 0**

To summarise, the following advantages render the "GALVANOSET" superior to all other methods:—

Nothing to get out of order.
No expense for upkeep.
Always ready for use.
Does not require re-charging.
Nothing to wear out.
Costs less than one farthing per hour to run.
Safe under all circumstances.
Finest range of adjustment.
Any desired current.
Light and portable.

**Some Features in**
**WATSON'S "VERSALIC" 1/12 in. OIL IMMERSION OBJECTIVE.**
**It has no equal for Laboratory purposes, and is particularly designed for hot climates.**

**Mechanical Points.**
The British Science Guild has recommended that Objectives should be sterilised before screwing home, to prevent growth of fungus, &c., in hot climates. This is done in the "Versalic" 1/12 in.
The B.S. Guild also recommended that the mounting should be of a colour to make the Lens easily distinguishable. The "Versalic" 1/12 in. is finished black.
In addition, the lenses are NOT set in their Cells with cement, which is apt to become unreliable, but all lenses are fixed with a metal bezel; they cannot therefore become displaced, the front lens cannot be "pushed in."

**Optical Points.**
Working distance of exceptional length—the maximum that can be given with maintenance of immersion oil contact. Unusually flat field. Corrected for use on stained objects.
Magnifying power is that of other 1/12 in. Lenses to which Laboratory workers are accustomed, viz. 1/12th in. It is a nominal 1/12 in. Definition is superb, and the Lens a pleasure to use.

**The Objective is British made.** It is designed for the Bacteriologist. It is especially recommended for hot climates. It will stand continuous rough working.

**PRICE £5. IMMEDIATE DELIVERY.**

WATSON'S MICROSCOPES are reliable and accurate. The demand exceeds the supply because their works are necessarily diverted to Optical Munitions. Inquiries are invited, and an approximate date for delivery will always be given.

## BRADFORD EDUCATION COMMITTEE.

TECHNICAL COLLEGE.

Principal—Prof. W. M. GARDNER, M Sc., F.I.C.

SPECIAL DAY DIPLOMA COURSES (3 or 4 years) in

(1) Dyeing and Textile Chemistry.
(2) General Industrial and Analytical Chemistry.
(3) Metallurgical Chemistry and Assaying.
(4) Chemical and Gas Engineering.
(5) Research in Textile Chemistry.

*Visits to Works* and the *solution of Works difficulties* are made special features.

DAY SESSION, 1916-17, has now commenced.

A pamphlet—"Industrial Chemistry and Dyeing as a Career for Men and Women"—post free on application.

Education Office, Bradford, October, 1916. BY ORDER.

## COUNTY BOROUGH OF HUDDERSFIELD TECHNICAL COLLEGE.

Principal—J. F. HUDSON, M.A., B.Sc.

CLOTH MANUFACTURE.
CHEMISTRY AND DYEING.
MECHANICAL AND ELECTRICAL ENGINEERING.
ECONOMICS AND COMMERCE.
BIOLOGY, PHYSICS, MATHEMATICS.

The new department of COAL TAR COLOUR CHEMISTRY is open for teaching and research under the direction of Dr. A. E. EVEREST.

Full particulars on application to the SECRETARY, Technical College, Huddersfield.

T. THORP, Secretary.

## SOUTH AFRICAN SCHOOL OF MINES & TECHNOLOGY, JOHANNESBURG

**(Under the University of South Africa Act, 1916, a Constituent College of the University of South Africa).**

The Council of the South African School of Mines and Technology invites applications for the following appointments, viz.:—

Department of English, Logic and Philosophy: PROFESSOR and ASSISTANT.
Department of History: PROFESSOR.
Department of Modern Languages:
(i) Dutch—PROFESSOR.
(ii) French—PROFESSOR.
Department of Classics: PROFESSOR and ASSISTANT.
Department of Education and Psychology: ASSISTANT.
Department of Economics:
Commercial Geography—ASSISTANT.
Department of Physics: PROFESSOR and ASSISTANT.
Department of Botany: PROFESSOR.
Department of Zoology: PROFESSOR.

A Three years' contract will be granted in each case.

Salaries: (a) Professors, £800 per annum, rising by annual increments of £50 to £900, and by similar increments to £1000 in the succeeding two years, where the appointment is confirmed and the member placed on the permanent staff; (b) Assistants, £350 per annum, rising by annual increments of £50 to the maximum of £450.

£75 will be allowed to Professors for travelling expenses to South Africa, and £50 to Assistants; half-salary will, in each case, be paid from date of sailing till arrival in Johannesburg.

The next session begins early in March, and the successful applicants will be expected to reach Johannesburg by February 15th, 1917.

The members of the staff have to supervise, and take part in, Evening work.

Applications in triplicate, stating age, professional qualifications and experience, as well as information regarding candidates' publications or researches, should, with copies of three recent testimonials, be sent not later than November 16th, 1916, to the undersigned, who, on application, will send a memorandum containing full information of the above appointments, and of the scheme for the expansion of University education on the Witwatersrand in the immediate future

Before appointment, the selected applicants will be required to pass a medical examination.

CHALMERS, GUTHRIE & CO., LTD.,
9 IDOL LANE,
LONDON, E.C.

## DEMONSTRATOR IN PHYSICS.

DEMONSTRATOR in PHYSICS required in January at the LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN, 8 Hunter Street, W.C.

Applications, with testimonials, to be sent to undersigned by Friday, October 27, from whom further particulars may be obtained.

L. M. BROOKS, Secretary and Warden.

## BIRKBECK COLLEGE,

BREAMS BUILDINGS, CHANCERY LANE, E.C.

COURSES OF STUDY (Day and Evening) for Degrees of the UNIVERSITY OF LONDON in the

## FACULTIES OF SCIENCE & ARTS

(PASS AND HONOURS)

Under RECOGNISED TEACHERS of the University.

**SCIENCE.—Chemistry, Physics, Mathematics (Pure and Applied), Botany, Zoology, Geology.**

**ARTS.—Latin, Greek, English, French, German, Italian, History, Geography, Logic, Economics, Mathematics (Pure and Applied).**

***Evening Courses for the Degrees in Economics and Laws.***

POST-GRADUATE AND RESEARCH WORK.

SESSIONAL FEES { *Day:* Science, £17 10s.; Arts, £10 10s. *Evening:* Science, Arts, or Economics, £5 5s.

*Prospectus post free, Calendar 3d. (by post 5d.), from the Secretary.*

## SOUTH-WESTERN POLYTECHNIC INSTITUTE, CHELSEA.

Day and Evening Courses in the Faculty of Science and Engineering.

Technical Chemical Courses.

Pharmacy and Dispensing Courses.

Particulars may be obtained on application to the Secretary (Room 44). SIDNEY SKINNER, M.A., Principal.

Telephone: Western 899.

## MATHEMATICAL TUTOR required in

January, able to prepare boys for Woolwich and Sandhurst. Stipend £180, with board and residence. Also CHEMISTRY TEACHER for County School. £160, non-res.—Address, GRIFFITHS, POWELL & SMITH, Tutorial Agents (Estd. 1833), 34 Bedford Street, Strand.

## THE HIGH COMMISSIONER for the UNION OF SOUTH AFRICA

invites applications for the CHAIR OF LOGIC AND PSYCHOLOGY at VICTORIA COLLEGE, STELLENBOSCH. Commencing salary £500; passage money; three years' agreement in first instance. Duties to commence middle February, 1917.

Applications, containing information as to age, character, qualifications, experience, health, and religious denomination, must be received not later than November 4, 1916, by the SECRETARY, Office of High Commissioner, Union of South Africa, 32 Victoria Street, S.W., from whom further particulars may be obtained.

## CRAWFORD MUNICIPAL TECHNICAL INSTITUTE, CORK.

Principal—J. H. GRINDLEY, D Sc.

The Cork Co Borough Technical Instruction Committee require the services of a LECTURER in CHEMISTRY. Salary £200 to £250 per annum.

Full particulars may be obtained from the undersigned, at his office, Sharman Crawford Street, Cork, by whom applications will be received not later than Saturday, October 28.

F. B. GILTINAN, Secretary.

October 11, 1916.

## LEICESTERSHIRE COUNTY COUNCIL.

### LOUGHBOROUGH TECHNICAL INSTITUTE.

WANTED IMMEDIATELY, LECTURER in ENGINEERING (preferably ELECTRICAL). Salary £150 to £175, according to experience and qualifications. The appointment is for the period of the War, but will probably be made permanent in the case of satisfactory service.

Applications, with not more than three copies of recent testimonials, should be sent to —THE PRINCIPAL, The Technical Institute, Loughborough, not later than November 1.

W. A. BROCKINGTON, Director of Education.

## WANTED ATTENDANT with Chemical

Laboratory Experience.—Box 190. c/o NATURE Office.

## FOR SALE.—"Nature," Sept. 27, 1906, to

Jan. 21, 1909.—Apply "ENGINEER," Technical School, Barnsley.

THURSDAY, OCTOBER 19, 1916.

## REMINISCENCES OF RAPHAEL MELDOLA.

*Raphael Meldola: Reminiscences of his Worth and Work by Those Who Knew Him, together with a Chronological List of his Publications, MDCCCLXIX–MDCCCCXV.* Edited by James Marchant. Pp. xv+225. (London: Williams and Norgate, 1916.) Price 5s. net.

ALTHOUGH the late Prof. Meldola's oft-repeated warnings to the nation on the decline of our chemical industries would fully entitle him to a place among the prophets, yet it could not truly be said of him, as was stated of the earlier seers, that he was "not without honour, save in his own country," for in spite of the distractions and anxieties of the present troublous times, more than twenty of his friends and colleagues, men eminent in their respective professions, have already in a few months contributed in his memory their tributes of appreciation and respect. These reminiscences of Meldola's worth and work have now been collected in a convenient volume which includes a chronological list of his original papers and other publications.

The biographical memoir by Sir William Tilden serves to emphasise the many-sided character of Meldola's scientific activities. Not only was he a brilliant chemist of wide experience, with special knowledge of synthetic dyes, but he was also a practical astronomer and a first-rate biologist.

A glimpse of Meldola's early days is furnished by Miss Neumegen, whose father taught him from the age of seven to fourteen years. His first chemical lecture was delivered at the age of fifteen to an audience of schoolfellows, of whom Sir Isidore Spielmann was one. Reminiscences extending over a period of forty years are contributed by Sir Edward Thorpe. Some of the incidents recorded have their humorous side, and testify to Meldola's sense of fun and love of the whimsical. His surpassing merits as professor of chemistry are cordially depicted by his former pupils, Dr. M. O. Forster and Prof. W. J. Pope, and by his colleagues of the Finsbury Technical College, where he presided over the chemical department for thirty years.

Prof. Green deals sympathetically with the classification of his technical and scientific researches. The technical investigations were often of a pioneer character. They opened up new ground, but in many cases the harvest was reaped in other countries. The first oxazine dye, "Meldola's blue," was not introduced into commerce in England, but was manufactured in Germany, where it became the forerunner of the still more important gallocyanine blues. His study of beta-naphthylated rosaniline led to a sulphonic acid which has since acquired importance in cotton dyeing. The researches on azo-dyes, although ignored in England, were utilised profitably by the astute colour-makers of Germany. His scientific chemical work can be classified under eight headings, of which the most important are the studies on azo- and diazoamino-compounds, and on substitution in the naphthalene series. In recent years Meldola and his assistants were engaged in studying imidazole and quinone ammonium bases, these researches being still in progress when death overtook him last November.

Prof. Poulton, who edits the bibliography of published works, contributes also an essay on Meldola as a naturalist. This appreciation contains many interesting reminiscences, some of which are published for the first time. Although Meldola received numerous scientific and academic honours from British sources, it is significant that during his lifetime he was even more appreciated in France. Twice he was offered a decoration of the Legion of Honour, and one learns with amazement that on each occasion the Foreign Office forbade him to accept this distinction!

Where so many distinguished contributors have united in a labour of love to place on record their happy recollections of this great teacher's work and personality, it would be superfluous to add more than that all these praises are worthily bestowed as a last fitting tribute to a life of high ideals and great accomplishment. It may, however, be mentioned that in addition to his published works and the grateful remembrances of his pupils, Meldola leaves behind another memorial in the form of a unique collection of research chemicals. The writer and two other former students of Prof. Meldola have spent a portion of the summer recess in arranging and cataloguing this collection, of which the specimens represent every phase in his career as chemical investigator. The preservation and study of these historical substances will constitute another method of keeping his memory green in the school of chemistry which he inspired and adorned for many years.

## ANIMA ANIMANS.

*The Breath of Life.* By John Burroughs. Pp. xi+295. (London: Constable and Co., Ltd., 1915.) Price 5s. net.

TWO ideas struggle for mastery in the mature reflections of this lover of nature and poetry: the one the super-mechanical and super-chemical character of living creatures, the other the continuity of natural processes and the universality of natural law. Living organisms transcend machinery; they are so persistent, insurgent, constructive, and inventive; but they are not possessed by any extraneous entelechy. They are solidary with the inanimate, though the creative energy or "procreant urge" finds freer expression in them than it does in crystal or star. It is a modernised hylozoism to which the essays composing this volume give beautiful expression: "The psychic arises out of the organic, and the organic arises out of the inorganic, and the inorganic arises out of—what? The relation of each to the other is as

Digitized by Google

intimate as that of the soul to the body; we cannot get between them even in thought, but the difference is one of kind and not of degree." There is much in the volume about the wonders of the inorganic domain, especially under the eyes of modern chemists and physicists, but the refrain is always what Tyndall called "the mystery and the miracle of vitality." Thus, to mention half of the fascinating studies, we have discussions of "The Breath of Life," "The Living Wave," "The Baffling Problem," "Scientific Vitalism," and "The Vital Order."

It is not easy to describe the life of the bee-hive without the postulate of psychical organisation, what Maeterlinck called the Spirit of the Hive; so to Burroughs it appears necessary to recognise a more than physico-chemical unity of the organism, in which the cells are the bees, and thus he speaks of the Spirit of the Body. But this vitality is potential in all matter, though it finds opportunity to manifest itself with emphasis in protoplasm. Vitality begins in the inmost sanctuary of the molecules, "but whether as the result of their peculiar and very complex compounding or as the cause of the compounding—how are we ever to know?" The striking essay entitled "A Bird of Passage" develops the idea that life plays a very small part in the total scheme of things, "the great cosmic machine would go on just as well without it." Yet it is only in the highest expressions of life that the total scheme of things acquires any meaning at all. And the author ends with the thought, which he knows to be beyond science, that there is a kind of universal mind pervading not only living matter, but the stuff of which the whole world has been spun. As the reader is warned in the preface, there is considerable reiteration in the course of the essays, but with a writer like Burroughs the impression left is that of music with a recurrent theme.

J. A. T.

## DIOPHANTINE ANALYSIS.

*Mathematical Monographs.* No. 16, *Diophantine Analysis.* By R. D. Carmichael. Pp. vi+118. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1915.) Price 5*s.* 6*d.* net.

THE remarkable thing about Diophantine analysis is that, although it is quite respectably old, it is still in that stage where the amateur is on an equal footing with the professional. If it be true, as we are inclined to think, that Fermat's last theorem admits of a Diophantine proof, this is as likely to be discovered by a schoolboy as by a professor steeped in all the lore of modern analysis.

Prof. Carmichael's book is welcome because it gives, either in the text or in the examples, a great deal of the actual results hitherto obtained; and the author has done something towards sorting out these results and adumbrating a real theory. In this respect chap ii. (on multiplicative domains) is the most valuable. Chap. v. gives a brief but up-to-date account of what is known about Fermat's last theorem. Important sections are those which treat of Fermat's methods of "descent" and of "double equations"; these, at any rate, are definite processes capable of extension to various cases.

The weak point of the book, in our opinion, is that the author never looks at a problem from a geometrical point of view. Of course, in the last resort, geometry is irrelevant; but in research it is very valuable. For instance, let $F(x, y, z)$ be a homogeneous cubic; then from the theory of curves we can conclude that if $F=0$ has an integral solution $(x_1, y_1, z_1)$, it has a sequence $(x_n, y_n, z_n)$ of integral solutions, which in most cases corresponds to a compact set of points on the curve $F=0$. The proof of this is most easily obtained from elliptic functions; there ought to be a purely Diophantine proof, but the difficulty is that we have to estimate the "nearness" of a solution $(x', y', z')$ to a solution $(x, y, z)$, and $(x_2, y_2, z_2)$ in the sequence is not generally "near" to $(x_1, y_1, z_1)$ in the geometrical sense. Again, if we have a unicursal surface, such as that given by the parametric equations,

$$x=\frac{a(\lambda\mu+1)}{\lambda+\mu}, \quad y=\frac{b(\lambda-\mu)}{\lambda+\mu}, \quad z=\frac{c(\lambda\mu-1)}{\lambda+\mu},$$

whence $x^2/a^2+y^2/b^2-z^2/c^2=1$, this suggests corresponding Diophantine theorems. Then, too, we have to consider solutions which, though not integral in the ordinary sense, are integral in certain algebraic fields; for instance, if $2\rho=-1+i\sqrt{3}$, then $(25-6\rho, 1-9\rho, 8+30\rho)$ is a solution of $x^3+7y^3-z^3=0$, which is integral in the field $(\rho)$, although it is not so in the field (1). In the latter field we have the solution (1, 1, 2); the reader is left to discover whether there are any other ordinary integral solutions, and if so, how many.

There are numerous exercises in the book which ought to stimulate the reader; some of them are practically suggestions for research. As a rule, it is unfair to expect a mathematical writer to give exact references to the sources of his examples; but in this case we wish Prof. Carmichael had been a little more definite, because in this subject even a short note on a very special problem may possibly contain the germ of an important discovery. As an instance of what we mean, Eisenstein's proof of the irreducibility of $(1-x^p)/(1-x)$, when $p$ is prime, is based on a theorem of his which must surely admit of some generalisation. To find whether any given polynomial is irreducible or not is practically such a laborious task (though theoretically possible) that special theorems like Eisenstein's are always welcome.

We hope that this book will have a wide circulation among mathematicians of all ages and capacities; it is rather a disgrace to the moderns that in this field they have added so little to the work of that great triumvirate, Diophantus, Fermat, and Euler.

## THREE TEXT-BOOKS OF PHYSICS.

(1) *A Manual of Practical Physics.* By H. E. Hadley. Pp. viii+262. (London: Macmillan and Co., Ltd., 1916.) Price 3*s.*

(2) *Text-book of Mechanics.* By Prof. Louis A. Martin, jun. Pp. xviii+313. Vol. vi: *Thermodynamics.* (London: Chapman and Hall, Ltd., 1916.) Price 7*s.* 6*d.* net.

(3) *An Intermediate Text-book of Magnetism and Electricity.* By G. F. Woodhouse. Pp. x+264. (Sedbergh: Jackson and Son, 1916.) 6*s.* net.

IT is always of interest to study text-books written by those engaged in teaching, and to note the special points which their experience as teachers leads them to emphasise.

(1) Mr. Hadley, who is principal of the School of Science at Kidderminster, is the author of a number of excellent works on physics, and the present small volume gives further proof of his ability as a clear exponent of physical principles. The book is suitable for the upper classes at schools where practical physics forms, as it should do, part of the science course. It is scarcely correct to say that it covers the work necessary for a present-day intermediate course, as many of the experiments described are qualitative rather than quantitative, and some are more suitable for the teacher to demonstrate in front of his class than for the students themselves to carry out. A noteworthy feature is the simple apparatus required for most of the work—the determination of the centre of gravity of a wickerwork basket suggests a new use for the editorial wastepaper basket!

It is open to question whether it is desirable to retain the definition of specific heat as a ratio (p. 116). In actual practice what is required most frequently is the "thermal capacity of unit mass," which is expressed in calories per gram per degree. Unless this is used the "dimensions" of an ordinary heat equation are incorrect. We may note in passing that for the same reason the value of a latent heat should be expressed, not in calories (p. 122), but in calories per gram. It has been pointed out in NATURE (vol. xcv., p. 427) that the British use of "specific" is hopelessly inconsistent, and it is only necessary to compare the definition of specific resistance on p. 225 with that of specific heat to appreciate the absurdity of our present nomenclature. A new term to denote the thermal capacity of unit mass of a substance is much to be desired.

A series of observations with an ammeter and tangent galvanometer is followed by the remark: "This demonstrates that the current is proportional to the tangent of the [illegible]." This is outline of the essentials of the subject. Although the treatment is elementary, differential equations are used throughout, their meaning being explained in such a way as to lead the student forward step by step. A large number of numerical exercises are provided throughout the work and at the end of the book. British thermal units are alone employed. The diagrams are very good, and the typography is such as to give every assistance to the student in his study of the subject.

(3) The "Intermediate Text-book of Magnetism and Electricity," by Mr. Woodhouse, senior science master at Sedbergh School, combines practical instruction with theoretical discussion. A large number of simple experiments described in the text may be carried out by the student with no great outlay in apparatus. The author is probably right in saying that the electrolytic definition of the unit of current is more readily grasped by the average student than the electro-magnetic, but we are of opinion that greater emphasis should be laid on the distinction between the practical definitions of electrical units (the so-called international units) and the absolute definitions. The book would be much improved by a careful revision: the style is frequently curt and sometimes inelegant. Many students have been penalised in examinations for giving as the second law of electrolysis: "The weight of an element deposited is proportional to the electro-chemical equivalent." The strength of a magnetic field is not measured in dynes (p. 53), but in dynes per unit pole or gausses.

We strongly endorse the opinion of the author that all students of physics should learn the calculus. A portion of Appendix I. is devoted to explaining, briefly, the principles and method of differentiating and integrating simple quantities. Several well-known text-books of physics are marred by attempts to evade the use of the calculus. It is far better to adopt the author's plan and devote a little space and time to introducing the elements of the calculus than to employ tedious and unnecessary investigations which are only differentiation or integration in disguise. Appendix II. contains a description by Mr. J. W. Shepherd of a wireless set which, in more favourable days than the present, may be set up by the student who has obtained permission from the Postmaster-General. H. S. A.

## OUR BOOKSHELF.

*Le Climat de la France: Température, Pression, Vents.* By G. Bigourdan. Pp. 135. (Paris: Gauthier-Villars et Cie.) Price 4 fr.

THIS publication, dealing particularly with tem-

Digitized by Google

stations in France at which the observations cover a period of fifty years, from 1851–1900, but fairly long periods are given for fifty-eight stations which constitute the principal values dealt with. Mean temperature charts are given for each month, and there are also seasonal charts for winter, summer, and for the year. Diurnal range of temperature is also dealt with. Barometric pressure is treated in a very similar manner to the temperature, and mean pressure charts are given for all months and for the year. A chapter is devoted to the disturbances of the atmosphere, and a detailed description is given of the general movement of cyclonic and anticyclonic systems. Maps are given showing the prevailing winds and the resultants for the four seasons of the year. M. Bigourdan provides a good *résumé* of the climate of France in about 130 pages, and the information is expressed in a popular manner, although its scientific accuracy is all that could be wished. The numerous charts enable the reader to obtain the several meteorological factors for any part of France.

*The Psychology of Relaxation.* By Prof. G. T. Patrick. Pp. viii+280. (London: Constable and Co., Ltd., 1916.) Price 5*s.* net.

ON the further side of the Atlantic one of the world's great peoples has been swept away by a passion for wild and crazy amusement; on this side the others are locked in the bloodiest war the world has seen: these are the phenomena, at first sight antithetically diverse, which Prof. Patrick brings together in his study of "relaxation." With them he sets the craving for alcohol, constantly rising in spite of prohibitive legislation, and—*longo intervallo*—the habits, widespread if not omnipresent, of laughter and profane language. In the author's view all these forms of human behaviour are, at bottom, illustrative of a single principle. The activities and relations of civilised life imply the upbuilding and functioning of extremely complex mental mechanisms, full of tensions, restraints, and inhibitions. To maintain these always in operation is an impossible task. From time to time, therefore, the complexes break up, and man falls back with relief into conduct expressive of simpler mental structures organised and consolidated in the far distant days of the race's childhood: he plays, he laughs, he swears, he fights. Alternatively, he seeks the same end—the temporary dissociation of his too complex mental mechanisms—by means of the narcotic power of alcohol.

Prof. Patrick finds much to say in defence of his thesis—even for his rather startling view of war as a gigantic "rest-cure"—and says it very well. The cautious reader will, however, feel that he has pressed a sound principle of interpretation much too far—that he has brought into clear relief one factor in the phenomena he analyses, but at the expense of neglecting others of equal significance. Still, *his* factor is undoubtedly one of great importance, and his exposition of its *rôle* is both informative and pleasant to read.

T. P. N.

## LETTERS TO THE EDITOR.

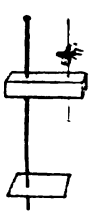
*[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.]*

### Elasticity and Entomology.

IN NATURE for June 22 (vol. xcvii., p. 340) there appeared an interesting letter under the above heading from the pen of Prof. Bryan. Perhaps I may be permitted to contribute some further remarks on the same subject, although my distance from the centre of Empire must necessarily entail a long delay before publication.

Unfortunately, the method of setting insects upon "Continental" pins does not appear to be "old-fashioned," for a large number of specimens received by me from all countries (excluding England, where, on the other hand, the insects are often set too low) are set in this obnoxious manner. In dealing with the same I always handle them by placing the forceps upon them under the insect, at a point only slightly above the level to which they are to be driven into the cork. Even so, the danger of vibrations, causing loss of antennæ, etc., cannot wholly be obviated. After many years' experience I have come to the conclusion that the shorter pins of English make, be they "silvered," "gold," or black, are in every way preferable to the long German pins. The insect should, however, be set at least half-way up the pin, and not so low down as is necessitated by the construction of many of the peculiar "curved" setting-boards still in use in England.

Using the numbers of the well-known "Kirby and Beard" make of pins, out of the following numbers which I have in use every day, viz. 1, 3, 5, 8, 15, 17, and 19, Nos. 1, 3, 5, and 8 may be classed as *stout*, and can be relied upon never to bend when inserted into cork or "lino," unless handled extremely roughly. Nor, so far as I can see, is there any deterioration in the elastic quality of such pins over a period of at least twenty years. On the other hand, Nos. 15, 17, and 19 must be classed as *slender* pins, and can never be relied upon, for certain, not to buckle under the pressure necessary to place the insect firmly in the cabinet. As all the smaller kinds of insects must be set upon one or other of these pins, or upon the even smaller silver-wire pins known as "caps," I have come to the conclusion that the only safe plan in all these cases is to use the Polyporus strips first suggested by Lord Walsingham—who, I believe, found this fungus growing in Merton Park, and ingeniously turned it to entomological use. As these strips are now sold by at least one firm in Australia, no doubt they are easily obtainable in England. A short piece of the strip is cut off and placed on a No. 8 pin, as shown in the illustration; the finer pin carrying the insect is gently inserted into the other end of the strip. The label may then be placed on the larger pin, below the strip, *facing upwards*, so that it can be read without moving the insect. I have a series of a new species of Coniopterygid, expanse only 3 mm., and the smallest Neuropterous insect known to me, set in this manner upon "caps," and they look extremely neat in the cabinet.



Returning to the subject of vibrations, might I suggest the use of a very simple expedient to obviate the constant breaking-up of the abdomen in those insects with long or fragile bodies, such as dragon-flies? This is the process of bristling, which I have used with success for years, but which I have never

Digitized by Google

seen adopted in the setting of specimens received from my brother entomologists. For large species the "bristle" should be a true hog's bristle of the kind obtainable at curriers'; for smaller, a stiff horse-hair. The "bristle" is sharpened by a diagonal cut with the scissors, and is then inserted between, and a little in front of, the mesocoxæ, and is run down to near the end of the abdomen, care being taken not to damage the appendages, and allowing a little space over for shrinkage during drying. It is then cut off close to the thorax. Even the soft-bodied Perlidæ can be much improved by this method.

R. J. TILLYARD.

Hornsby, N.S.W.

### Early Use of the Word "Blizzard."

IN a communication to NATURE of June 22 (vol. xcvii., p. 341) Mr. Miller Christy states that the first appearance of the word "blizzard" in "permanent literature" was in 1885, when he used it in his work, "Manitoba Described," and that the description of the phenomenon therein by Mr. Thompson Seton was the earliest ever published.

As one of the American meteorological specialities, the blizzard has always received attention by the Canadian and United States Weather Bureaus. The very earliest use of the word has not yet been ascertained, but it has been found in current use as the name of the storm Mr. Christy describes, at least as early as 1867. In that year the *Dakota Republican* published, at Vermilion, Dakota, an account of the blizzard that suddenly approached that town, and called the storm by *that name as one in common use* when applied to a sudden change from warm and balmy weather to a blinding snow with cold north-west winds.

The earliest known description of "blizzard" phenomena seems to have been that by Henry Ellis in his account of his visit to Hudson's Bay in the *California* in 1746, and his winter at York Factory. However, Ellis did not apply the name "blizzard" to the storms he described.

Brief notes on the name "blizzard" will be found in the *Monthly Weather Review*, Washington, December, 1898, p. 562; January, 1899, p. 18; and December, 1914, p. 692.

The name "blizzard" for "a cold-wave gale with very low temperature and fine driving snow" is recorded by C. A. Lounsberry as being in use in Dakota, Iowa, and Minnesota as early as 1865. The *American Meteorological Journal*, July, 1886, pp. 112–14, quotes an excellent description of the blizzard by Mr. Lounsberry in the *Northwest Magazine*.

OTTO KLOTZ.

Dominion Observatory, Ottawa, October 2.

## THE FUTURE OF THE ZINC-SMELTING INDUSTRY IN GREAT BRITAIN.

IN 1913 the world's production of the metal zinc, or, to give it its trade name, spelter, was 985,142 English tons (2240 lb.). Of this Great Britain produced 58,298 tons, *i.e.* 5·9 per cent. On the authority of Moulden,[1] however, it may be stated that "probably not more than 31,290 tons were 'primary' spelter in the sense of being extracted from ores, the balance of 27,008 tons being the result of treatment of by-products, galvanisers' ashes, hard-spelter, etc." In the same year Great Britain imported 145,004 tons of spelter, which, at the average ruling price, "ex ship," represents a total value of 3,291,772*l.* In other words, this country in the year before the outbreak of war was producing—even including "secondary" metal—only 30·1 per cent. of its spelter requirements. The galvanised iron industry absorbed about 60 per cent. of the above production, the manufacture of brass from 20 to 25 per cent., while the remainder was used for the manufacture of sheets, alloys other than brass, etc.

The bulk of the spelter imports was obtained from Germany and Belgium, each of them a large producer of the metal, and each of them a large importer of zinc ore from the most important zinc mine in the British Empire, at Broken Hill, Australia. This ore consists of an intimate mixture of argentiferous galena and blende occurring in a gangue chiefly composed of rhodonite, quartz, and garnet. It is treated by concentration and separation processes so as to give two main products, a lead ore and a zinc ore concentrate, the latter containing about 46–48 per cent. of zinc with certain values in lead and silver. The output of zinc concentrates before the war was about 500,000 tons annually. Apart from the ore which was smelted at Port Pirie, and about 20,000 tons which were sent to England and smelted at the Sulphide Corporation works at Seaton Carew, "the whole of the zinc concentrates in the past has been sold under long-term contracts to smelters in Belgium and Germany."[2] The Germans had acquired a controlling interest in the most important Belgian works, and, according to Moulden, utilised this control to make money, which they did by passing the greater part of their concentrates on to the Belgian works for smelting. "Of the total Australian output Belgium smelted at least 75 per cent. and Germany only 14 per cent."[3]

On the outbreak of war in August, 1914, the following situation arose:—

(1) Germany was unable to take delivery of Broken Hill concentrates owing to the command of the seas which Great Britain immediately obtained and has ever since held.

(2) The Belgian works, which soon fell into German hands as a result of the military invasion, were equally unable to receive their share of the concentrates.

(3) Australia thus lost nearly all her market for zinc concentrates.

(4) Great Britain was deprived of by far the greater part of her imports of spelter.

Great Britain thus found herself in the anomalous and dangerous position that, with the command of the seas and an immense supply of zinc ore in the Empire, there was, owing to the lack of smelting works, no prospect of converting it into metallic zinc; and zinc as a constituent of cartridge brass is an indispensable munition metal. It is, of course, obvious that such a situation should never have been allowed to arise, and it will naturally be asked why should not all

[1] Le Neve Foster Prize Essay. Journal of the Royal Society of Arts, 916, p. 526.

[2] Smith, "The Development of the Spelter Industry." Journal of the Institute of Metals, No. 2. 1016.

[3] Journal of the Royal Society of Arts, 1916, p. 528.

Digitized by Google

the Broken Hill concentrates have been treated in the British Empire. The answer is that they could have been, they should have been, and perhaps they may yet be.

The effect of the above situation was felt more quickly in Australia than in Great Britain. The mines, deprived of the greater part of their market, had to curtail production very considerably, and it is to their credit that, in order to minimise hardships among their labouring population, they continued to produce considerably more ore than they could for the time being dispose of. It was not until the spring of 1915, when the Ministry of Munitions was created in this country, and it was realised upon what a gigantic scale it would be necessary to manufacture cartridges, shells, etc., that the extent of the shortage of zinc became apparent. Moreover, the zinc famine was not confined to Great Britain. France could produce nothing like her requirements, Russia and Italy still less, Belgium and Serbia none at all.

With one accord the Allied countries turned to the United States of America, the largest producer of zinc in the world, and it is no exaggeration, but the simple truth, to say that that country saved the situation. Her zinc smelters have been very highly paid for their services. For many months Great Britain was obliged to pay more than 100*l.*, and sometimes 125*l.*, a ton for metal which normally costs between 22*l.* and 25*l.* But the dominating fact is that no other nation could have come to the rescue in the way the United States did. In 1913 they produced 320,283 metric tons of zinc (2204·6 lb.); they consumed 313,300. The balance available for export was thus 6983 tons. In other words, the American smelters had practically no balance available, and had to create with the utmost rapidity conditions which would enable the very large demands of the Allies to be met. Mr. W. R. Ingalls, one of the greatest authorities on zinc smelting in the United States, estimates [4] that the spelter production in 1915 was 452,000 English tons, and that for 1916 an output of at least 714,000 tons seems assured. What these figures mean can be adequately appreciated only by those who know what is involved in the expansion of an industry where mining and ore-dressing operations, transport and assemblage of materials, erection and operation of furnaces, and, most difficult of all, the training of the necessary labour are concerned. Mr. Ingalls contents himself with remarking that "the manner in which our spelter production in 1915 was expanded is one of the romances of our industry."

Canada and Japan have increased their output of zinc to a considerable extent, but the augmentation of output in Great Britain and Australia has not been large. What is going to be the future of the zinc-smelting industry in this country? This is the question which has been exercising the minds of those who have the welfare of this industry at heart ever since the lamentable and dangerous situation at the outbreak of war was revealed. There is no doubt at all that Great Britain can become, and indeed ought to become, one of the greatest centres of production of spelter in the world. But is she going to, and are steps being taken to see that she shall? Certain considerations appear to bear on this question, and an enumeration of them may perhaps aid in presenting the situation as it appears to the writer.

(1) No zinc concentrates will be shipped to Germany in future. Australian legislation, confirmed by the House of Lords, has decided this. The Australian mine-owners will therefore have to find fresh markets for that proportion of their ore which previously went to Germany.

(2) Germany, in spite of the length of time that her own ore deposits have been worked, still has large supplies. She has also considerable zinc-mining interests in China, and before the war shipped zinc concentrates from that country. She will not fail to develop her trade in this direction after the war, and will continue to be an important producer of spelter.

(3) The United States zinc smelters will be very formidable competitors after the war. They have used their large profits wisely in making their plants efficient and up-to-date, and in accumulating large financial reserves. Their present rate of production is sufficient for more than 70 per cent. of the world's peace requirements before the war. They will have considerable tonnages of the metal available for export. They have very large ore supplies, not only of "straight" zinc ores, but of the complex ores in which zinc blende is associated with galena and other metallic sulphides, and which now constitute an increasingly important source of spelter. It is very unlikely, therefore—quite apart from the 10 per cent. *ad valorem* tariff to which zinc ores imported into the United States are liable—that Australian zinc concentrates will find a market in America.

(4) The Canadian Government is encouraging zinc smelting by granting bounties on zinc produced in Canada from Canadian ores. Australian concentrates are, therefore, not likely to enter Canada to any great extent.

(5) The future of the Belgian industry is quite uncertain, but it is much to be hoped that it will be re-established after the war, and in this case, as it will depend largely on imported ores, there may be a renewal of the contracts with the Broken Hill mine-owners.

(6) By virtue of the magnitude of its population, its transport facilities, markets, and the raw materials necessary for zinc smelting—apart from the ore itself—Great Britain is the most suitable country for the treatment of Broken Hill concentrates exported from Australia. The Swansea district is one of the most favourably situated places in the world for the production of zinc, and is the chief seat of the British industry.

The complete treatment of Broken Hill concentrates involves, however, more than the mere production of zinc. They are a potential source of (1) sulphuric acid, (2) zinc, (3) lead, and (4

[4] *The Engineering and Mining Journal*, April 1, 1916.

Digitized by Google

silver, and should be worked up to produce all of these. This being so, it does not follow that the roasting of the ore for acid should necessarily be carried on at the same place as the smelting of the roasted material for the metals. Moreover, it is just the fact that this ore is a potential source of acid which renders it necessary for the bulk of the concentrates to be shipped from Australia, where the market for acid is limited, to a country like Great Britain, with nine times the population of Australia, and highly developed industries which can absorb the acid.

Stated broadly, if Great Britain is going to produce all the zinc needed for home consumption, the output of "primary" spelter will have to be increased at least fivefold. At present neither electrolytic zinc nor electro-thermally distilled zinc can compete commercially in this country with that obtained by distillation with coal in externally fired retorts heated by gas. Unquestionably the most difficult part of the problem is the training and organisation of the labour required for this process. Difficult though this is, it should be undertaken without delay, for America has shown that it can be done, and done rapidly when necessary. The establishment in this country of a zinc-smelting industry on a scale commensurate with its needs is most urgently required. There is no reason, if there is a proper application of organising ability, technical knowledge, perseverance, and resourcefulness—such as is now being exhibited on the British battle-front—why success should not be achieved. It would be an industrial victory of the first magnitude, and it would remove a peril in which this country was placed by the outbreak of war, which has been all too imperfectly realised, and should never be allowed to recur.

No reference has been made in this article to the possibility of assistance to be given by the British Government. As already mentioned, the Australian Government has dealt with the situation created there, and the Prime Minister, Mr. Hughes, is credited with having a very definite policy as to the future of the zinc mining and smelting industry, a policy in which Australia and Great Britain are immediately concerned. Whether and to what extent the statements relative to this which have appeared in the Press are trustworthy and authentic it is impossible to say. Some of them have been so inherently improbable that it is wisest to suspend judgment until the matter has been settled and an authoritative announcement made. There is every reason why there should be as little delay as possible in reaching a decision and acting upon it.

H. C. H. CARPENTER.

## *PROF. PIERRE DUHEM.*

THE precise formulation of the fundamental principles of mathematical physics may be said to be the outstanding feature of the work of Pierre Maurice Marie Duhem, whose sudden death at Cabrespine (Aude) on September 14 was announced in NATURE of September 21.

Born at Paris on June 10, 1861, Duhem in due course graduated in science, and for many years past held the chair of theoretical physics in the University of Bordeaux.

Although for a considerable time a corresponding member of the Academy of Sciences, it was not until 1913 that the distinction of full membership was conferred on him

Unlike most physicists, who take as their starting-point the equations of reversible dynamics, Duhem commenced with thermodynamics, and his treatise on the Thermodynamic Potential, published in 1886, will always remain a classical work of reference on the subject. At that time the work of Willard Gibbs (1876–8) was beginning to attract attention to the potentialities of thermodynamics in relation to chemical theory, and Duhem became an early exponent of the new methods. In 1893 he published his "Introduction à la Mécanique chimique," which was followed in 1897–9 by a much more comprehensive work in four volumes, entitled "Traité élémentaire de mécanique chimique fondée sur la Thermodynamique."

A large portion of this work is in a high degree original. We may instance the detailed studies of ternary and other mixtures and the use of trilinear co-ordinates in this connection as one of the interesting features of the work, but perhaps the most remarkable sections are those dealing with false equilibria and explosions, in which the author abandons the limitations of "classical mechanics" and invokes the assistance of a retardation analogous to friction in explanation of the observed phenomena. About the same time also appeared his "Cours de physique mathématique," dealing with hydrodynamics, elasticity, and acoustics.

The more technical applications of Duhem's work on physical chemistry form the basis of his "Thermodynamique et Chimie," which appeared a little later, and has been translated into English. In 1911 Duhem endeavoured to unite thermodynamics and mechanics in a comprehensive treatise on energetics covering statics, dynamics, hydrodynamics, elasticity, and physical chemistry. In a series of smaller contributions, entitled "Recherches sur l'Hydrodynamique," Duhem gave a detailed discussion of certain aspects of the study of fluid motions.

If the properties of matter occupied so large a place in Duhem's work, electricity was by no means overlooked. A volume of 228 pages, published in 1902 (Paris: A. Hermann), is devoted to a critical and historic study of Maxwell's electric theories. About the same time appeared the volumes in commemoration of the twenty-fifth anniversary of the doctorate of H. A. Lorentz (1900), and the sixtieth birthday of Boltzmann (1904). To the former Duhem contributed a paper on Helmholtz's electrodynamic theories and the electromagnetic theory of light, while to the latter he presented in June, 1903, an important contribution on the problem of electric stability.

Historical studies would likewise appear to

Digitized by Google

have had considerable attraction for Duhem. On the origins of statics he published two volumes, but the crowning work of Duhem's later years would appear to be a work of ten volumes on the history of astronomy up to Copernicus, of which so far only four have appeared.

The writer of this notice visited Duhem at Bordeaux in 1901. He was a shortish man with a very pleasing manner, in which could be observed that element of preciseness which characterises his writings. It will readily be understood that a vast laboratory fitted with costly and complicated apparatus was not needed by a mathematical physicist like Duhem, and it was interesting to compare the simple equipments at Bordeaux with the rather less simple, but more dusty, pieces of apparatus used by another mathematical physicist, Ludwig Boltzmann, at the dingy buildings in the Türkenstrasse at Vienna. But if Duhem did not indulge in superfluous luxuries, he made the best use possible of all the essential apparatus, and on the occasion of the visit he demonstrated the then newly discovered properties of radio-active substances with the same care and attention to detail that are so noticeable in his theories.

If Duhem did not concentrate his main efforts on the discovery of new phenomena or the measurement and re-measurement of physical constants, he has at least played an equally important part in the advancement of our knowledge by evolving order out of chaos, and uniting isolated portions of mathematical physics in the form of a connected and logical theory.

G. H. BRYAN.

## NOTES.

A MEETING to consider the steps to be taken to raise a memorial to the late Sir William Ramsay will be held at University College, London, on Tuesday, October 31, at 4.30 p.m. Invitations will be sent out on or about October 20. It will, however, greatly help in making the arrangements if all persons wishing to be present, including in particular scientific friends and former students of Sir William Ramsay, will send a postcard to the secretary, University College, London, intimating their desire. Those who thus apply will not be asked to reply to the invitation when issued. Further particulars of the arrangements for the meeting will be issued in a few days. After the meeting the director of the University College Chemical Laboratories, Prof. J. Norman Collie, will deliver a memorial lecture on "The Scientific Work of Sir William Ramsay," at 5.30 p.m.

THE annual Huxley Memorial Lecture of the Royal Anthropological Institute will be delivered on Tuesday, November 14, by Sir J. G. Frazer; the title of the lecture is "Ancient Stories of a Great Flood."

MR. H. G. NAGEL and Mr. A. D. Hall have been appointed members of the Government committee which is considering the question of the teaching of science.

WE learn through the *Electrical Review* that it has been decided, owing to the war, not to hold the Hobart meeting of the Australasian Association for the Advancement of Science, which had been arranged for January, 1917.

THE meetings of the London Mathematical Society will be held during the session 1916–17 in the rooms of the Royal Astronomical Society, Burlington House, W. They will not always be on the second Thursday of each month, as hitherto, but on dates and days announced by the council in the list just issued.

THE twenty-fourth "James Forrest" lecture of the Institution of Civil Engineers will be delivered on Tuesday, October 24, at 5.30 p.m., by Sir John Purser Griffith. The subject will be "The Development of Appliances for Handling Raw Materials and Merchandise at Ports and other Large Centres of Traffic."

THE death is recorded in the *Revue Scientifique* of Dr. Valentin J. J. Magnan, a leading French authority on mental disorders. Dr. Magnan was elected a member of the Paris Académie de Médecine in 1893, and became president in 1915. He was the author of "Leçons cliniques sur les Maladies mentales."

THE death is announced in action on September 28 of Capt. E. J. Smith, Duke of Wellington's Regiment. Before joining the forces, at the outbreak of war, he was senior science master at Sexey's School, Blackford, Cheddar. While in Gallipoli he was shot through the shoulder when in command of the snipers of his battalion. Later he commanded the Brigade Bombing School at Suvla Bay.

THE Hippurite from the chalk near Faversham, noticed in our last issue, has now been placed, with some other illustrative specimens, on exhibition in the Gallery of Fossil Reptiles at the Natural History Museum, since the galleries containing fossil invertebrates are closed to the public.

REPORTS from the Swedish expedition to Spitsbergen, noticed in NATURE for July 27 (p. 448), show that valuable work has been done, especially in the detailed mapping of the district. Besides conducting the investigations previously mentioned, the expedition has made several excavations in the old moraines on the shore, resulting in the discovery of deep-seated ice, many thousands of years old. How thick a covering of rock such fossil ice can support is a question worth solving. At any rate, deep borings have proved that it does not continue under the floor of the harbour. A Norwegian expedition to Spitsbergen, which has been investigating the Svalbard Company's coalfield, reports that it is of colossal size, containing, according to calculation, as many as 880 million tons. Norway's yearly consumption of coal is 2·8 million tons.

REPLYING, in the House of Commons, to a question by Mr. Ashley, M.P., on October 12, Mr. McKinnon Wood said:—"The direct savings resulting from closing the national museums and picture galleries to the public are estimated at approximately 50,000*l.* per annum, in addition to which a large economy results from freeing staffs, and in several cases accommodation, for purposes of immediate national importance at the present time." The sum named is that which was put forward by the Government when the proposal was first mooted, and, relatively small though it be, it is satisfactory to learn that this regrettable step has actually resulted in such direct addition to the National Exchequer. It must not, however, be forgotten that the museums in question had already forgone their purchase grants and had in other directions greatly reduced their expenditure, while continuing to perform, as exemplified in our last issue, important national services. It would be interesting to compare the actual expenditure on museum work at the present

Digitized by Google

time with the pre-war expenditure. In such a comparison the salaries of all employees now on war service would, of course, be deducted.

DR. J. S. FLETT, F.R.S., will deliver the Swiney lectures this year. The subject selected by the trustees of the British Museum, "The Mineral Resources of Europe," is very appropriate to the circumstances of the time. The lectures, twelve in number, will be delivered in the hall of the Royal Society of Arts, commencing on November 14. Dr. Flett will deal with the coal resources, petroleum, iron ores, copper, tin, lead, and the precious metals of all the European countries, and one lecture will be devoted to the salt deposits of Germany, France, and Great Britain, and to a general review of the mineral resources of the countries of Europe, and their importance in the world's trade and industry.

A REMARKABLY fine skull of the Cretaceous horned dinosaur, Monoclonius, has just been added to the remains of fossil reptiles exhibited in the Geological Department of the British Museum (Natural History). The specimen, which measures nearly 5 ft. in length, was discovered by Mr. W. E. Cutler in the Belly River formation of Alberta, Canada, and is interesting for comparison with the still larger skull of Triceratops from Wyoming, U.S.A., already in the museum. Monoclonius is peculiar in having the largest horn on the nose, only diminutive horns above the eyes, while its extensive bony frill over the neck is pierced by two vacuities and provided behind with a pair of remarkable forwardly directed prominences. The brain-case of the fossil is especially well preserved, and a plaster cast of the cavity shows the usual diminutive size of the brain.

WE regret to learn from the *Revue Scientifique* that Dr. Jean Boussac has died from wounds received in action in France. Dr. Boussac, who was born on March 19, 1885, was one of the most active and brilliant geologists of the younger French school, and had done much important work for the Geological Survey of France. He was especially interested in the Eocene Nummulitic formations, and had travelled extensively in Europe and Egypt while attempting to correlate these deposits. His stratigraphical researches led to interesting results in understanding and restoring the oceanography of Eocene times. He also undertook a revision of the species of Nummulites to facilitate their use in geological work, and made many valuable observations on the evolution of the shells of the Cerithiidæ. All Dr. Boussac's researches were characterised by marked originality, and his death causes a serious loss to geological science.

THE Norwegian explorer, Dr. Carl Lumholtz, has recently returned from a prolonged journey in the heart of Borneo. From the *Daily Chronicle* we learn some details of his work. After spending two months among the Murang Dyaks, he started on his journey to central Borneo in December, 1915. The route was from Banjermassin up the Barito and the Busang to the Müller mountains, thence by the Mahakkan river back to the coast. Dr. Lumholtz's work includes a new map of the watershed region of central Borneo and anthropological and photographic records of the Dyaks of the Upper Mahakkan. He has also brought back large ethnographical and zoological collections. The expedition reached Samarinda on August 22 this year.

says that he proposes to leave New York this month for Brazil, and to ascend the Amazon and Rio Negro to Santa Isabel, pushing on thence by steam launch to the Guainia. He hopes to reach the sources of the Guainia, which lies between the Papunaua branch of the Inirida and the Isana. Further, he proposes to survey and map the Casiquiari, which links the basins of the Orinoco and Amazon, and to solve some of the hydrographical problems of this region. Dr. Rice hopes to determine some longitudes with the help of wireless telegraphy, and to effect barometric determinations of altitude which will form the basis for a more accurate knowledge of the hypsometry of this part of South America than exists at present.

PROF. VINZENZ CZERNY, news of whose death, at seventy-four years of age, was received last week, was professor of surgery at Heidelberg University, and director of the Institute for Cancer Research in the same town. At the commencement of his career he showed for the first time that normal life was possible after extirpation of the stomach by operations on two dogs, one of which was alive and well five years later. Apart from his eminence as a surgeon, he will chiefly be remembered by his exertions in founding the Institute for Cancer Research at Heidelberg, of which he was the first director, a task to which he brought all the energies of an enthusiastic and generous personality. He was president of the International Conference on Cancer Research held in Paris in 1910, under the patronage of the President of the French Republic.

BY the death, in Edinburgh, of Dr. James Burgess, at the age of eighty-four, India has lost a veteran archæologist. Arriving in India before the Mutiny days, he was engaged in educational work at Calcutta and Bombay. But his bent for archæology led him to found the *Indian Antiquary*, which, since 1872, has taken a leading part in antiquarian and linguistic research. In 1874 he was placed in charge of the Archæological Survey of Western India, and at the close of his official career he had held for three years the post of director of the Archæological Survey of India. His original work was chiefly confined to his careful survey of the antiquities of Gujarat, and he published useful monographs on Elephanta, Somanath, Junagadh, and Girnar. He was closely associated with the great architect and antiquary, James Fergusson, and collaborated with him in the work on the "Cave Temples of India." It was near the close of his literary career that he undertook a new edition of Fergusson's standard "History of Indian and Eastern Architecture," with somewhat disappointing results. It is on his work as a careful and energetic field-worker in the survey of Indian antiquities that his reputation mainly depends.

THE death on September 11, at the age of twenty-five, of Second-Lieut. Archibald W. R. Don, while on active service abroad, deprives the scientific world of one who showed exceptional promise. He was the fourth son of Mr. and Mrs. R. B. Don, of Tealing House, Forfarshire, and The Lodge, Broughty Ferry. Educated at Winchester and Trinity College, Cambridge, he won a major scholarship at the latter, and graduated first class in the Natural Sciences Tripos in 1912. He was much loved and respected in a wide circle of undergraduates and senior members of the University, where his great influence was ever exerted for good. He devoted his attention to geology early in life, but

Digitized by Google

had already written, with Dr. G. Hickling, a paper on the problematical *Parka decipiens*, which was read before the Geological Society, but is not yet published. He obtained a commission in the Black Watch in December, 1914, and while on service at home and abroad collected geological specimens for the Sedgwick Museum.

THE council of the Chemical Society has arranged for three lectures to be delivered at the ordinary scientific meetings during the session 1916–17. The first of these lectures, entitled "Alloys of Copper and Tin, Aluminium and Gold," will be delivered on January 18 by Col. C. T. Heycock, F.R.S. On March 15 Dr. Horace T. Brown, F.R.S., will lecture on "The Principles of Diffusion: their Analogies and Applications"; and the third lecture, entitled "Some Main Lines of Advance in the Domain of Modern Analytical Chemistry," will be given on May 17 by Mr. A. Chaston Chapman. The ordinary scientific meetings commence at 8 p.m. In order to afford facilities to fellows for meeting each other informally, the council has again arranged to hold three informal meetings during the session, on October 19, 1916, and on January 11 and May 10, 1917. The council will gladly welcome any offers of assistance from fellows willing to show experiments and apparatus at these meetings, and such offers should be made to the assistant secretary not later than the Monday previous to the meeting.

THE gift of the Wright aeronautical patents to the British nation has caused some comment in the Press. Without in any way underestimating the magnificent pioneer work of the brothers Wright, it must be admitted that the majority of the ideas covered by their patents are now out of date. One of the main patents is connected with the warping of the wings, and the interconnection of the warp and rudder controls. At the present time warping has been almost entirely superseded by the use of wing flaps, which are more effective aerodynamically, besides being much easier to design from a mechanical point of view. Patents connected with automatic stabilisers are also useless, for machines can now be built which are inherently stable, both longitudinally and laterally, so that the necessity of an automatic stabiliser is removed. The Wrights themselves seemed to think that such a stabiliser was unnecessary. The action of the Wright Company in accepting 15,000*l.* compensation instead of proceeding with their action against the War Office for infringement was highly laudable at a time when the co-operation of all aeronautical firms was so much needed. It seems doubtful, however, whether the gift of their patents to the nation will produce any great benefit at the present stage of the development of aeronautics

THE thirteenth memorandum of the Health of Munition Workers Committee, which has just been issued, deals with juvenile employment. It is pointed out that the hours of work are extremely long—sixty hours a week—and that in many cases this limit has been exceeded, and the weekly hours have been extended to sixty-seven hours, or even longer. The long hours of work react unfavourably on the health of the workers, not only owing to the physical strain involved in the work, but also because the limited opportunities for recreation often lead to deterioration of character. These harmful effects are clearly more liable to occur in the young, whose development is still incomplete and whose character is not yet formed and stable. The committee recommends the abolition of Sunday work, and, except in special circumstances, of night work. It does not feel justified, however, under the present conditions, in suggesting the limitation of the hours of work to less than sixty hours weekly for those under sixteen, and sixty-five hours for those above sixteen years of age. A further excellent suggestion is the appointment of visitors, whose work is directed to improving the physical and moral welfare of the boys in factories by organising facilities for recreation, by personal supervision, and by direct association with the boys; this plan has already been adopted in at least one factory.

THE Secretary of State for India has authorised the Indian Committee of the Imperial Institute to inquire into and report on the possibilities of extending further the industrial and commercial utilisation of Indian raw materials in this country and elsewhere in the Empire. The committee has already commenced its work and has appointed a number of sub-committees to deal with the more important groups of materials, to consider the results of investigations and inquiries already conducted by the Imperial Institute, and to obtain the views of leading merchants, manufacturers, and other users of the raw products of India. One of the important aspects of the committee's work will be to suggest openings for the employment of those Indian materials which before the war went to enemy countries. The Indian Committee of the Imperial Institute includes Lord Islington (Under-Secretary of State for India), Sir Marshall Reid (member of the India Council), Prof. Wyndham Dunstan (director of the Imperial Institute), Mr. L. J. Kershaw (secretary, Revenue and Statistical Department, India Office), Sir John Hewett (formerly Lieutenant-Governor of the United Provinces), Mr. G. B. Allen (of Messrs. Allen Bros. and Co. and Messrs. Cooper Allen, Cawnpore), Mr. Yusuf Ali (late Indian Civil Service), Sir R. W. Carlyle (lately member of the Viceroy's Council), and Sir J. Dunlop Smith. Mr. C. C. McLeod, chairman of the London Jute Association, is chairman of the committee, and the secretary is Mr. A. J. Hedgeland, of the Imperial Institute.

MR. F. R. ROWLEY, the curator of the Royal Albert Museum, Exeter, has contributed some valuable notes to the *Museums Journal* for October on objects preserved in arsenious acid glycerine jelly. His method is an adaptation of, and an improvement on, that devised by Prof. Delépine. The advantage of this method of preservation is purely one of convenience, since it affords a means of avoiding the introduction of spirit, or other fluid preservative, among dry preparations. The successful preservation of colour varies according to circumstances, but experiments with seaweeds have given extremely satisfactory results. So far, however, this medium has failed in regard to flowers.

THE relationship between the geographical distribution of megalithic monuments and ancient mines is discussed at length in an able essay by Mr. W. J. Perry in the Memoirs and Proceedings of the Manchester Literary and Philosophical Society, 1915–16. The author contends that the weaving of linen, the use of pearls, precious stones and metals, and of conchshell trumpets, are all accompaniments of the megalithic culture, which had its origin in Egypt. Thence it spread through Europe to Britain, on one hand, and eastward through India and the East Indian Archipelago, and thence out across the Pacific by way of the Carolines, Solomons, New Hebrides, Fiji, and Easter Island to America. The agents in this distribution were the Phœnicians, and the part they played in this is discussed at length by Prof. G. Elliot Smith in an appendix to Mr. Perry's paper. Herein evi-

Digitized by Google

dence, which seems to be beyond dispute, is produced to show that the Phœnicians played the part of distributing agents of this culture, and not that of missionaries. The search for wealth was the underlying factor in this distribution, and provided the motive for the widespread travellings of these people. To assist in this search they employed expert gold-miners from the Black Sea and from Colchis, hence the megalithic monuments in the mining camps. That these two contributions will give rise to much discussion in the immediate future need scarcely be said, for the theme is one of first-rate importance; but there can be little doubt that the views they have so skilfully expressed will meet with general acceptance.

SPORADIC migrations of butterflies, moths, and dragonflies have long been known, and have generally been regarded as comparable to the similar migrations of locusts. But Mr. Howard J. Shannon, in the *Scientific Monthly* for September, under the title "Insect Migrations as Related to Those of Birds," has marshalled a host of facts which apparently show that certain North American species of butterflies, diptera, and dragonflies annually migrate southwards in the autumn, following well-defined routes corresponding to those taken by the birds of the same regions. The author does no more than hint at a return migration in the spring, expressing curiosity as to whether such migrants are of the same individuals which passed southwards in the autumn, or whether they represent a new generation, bred in the southern winter quarters. Some idea of the magnitude of these migrations may be gathered from the author's statements in regard to the monarch butterflies (*Danais archippus*), which, "in mingled myriads, move forwards . . . in swarms . . . forming veritable crimson clouds . . . miles in width and streaming backwards for equal distances . . . casting below them as they go perceptible shadows."

UNDER the modest title, "Notes on Some Palæozoic Fishes," Messrs. D. M. S. Watson and Henry Day have enriched the Memoirs and Proceedings of the Manchester Literary and Philosophical Society with a contribution of first-rate importance. They have described and figured in detail the skulls of Holoptychius, Glyptopomus, and Osteolepis, and the whole fish of *Rhizodopsis*. These studies have shown that the Rhipidistian skull is considerably more complicated than has previously been supposed, and that the short type of paired fin found in Eusthenopteron is older than, and has given rise to, the biserial "archipterygial" fin of Holoptychius. In Rhizodopsis and Glyptopomus they have given an account of the palate which considerably extends our knowledge of the structure of this region, and has a very important bearing on the problem of Amphibian ancestry. Further, they show that Ceratodus is derived by a process of specialisation and reduction from Dipterus, while Uronemus and Ctenodus are shown to belong to different lines of descent, and the conclusion is reached that *Dipterus valencennes* is the most primitive, as it is the oldest, known Dipnoan.

DR. C. A. BARBER, sugar-cane expert to the Government of India, describes, in a recent number of the Memoirs of the Agricultural Department of India objective, and is also handicapped by unsuitability of soil, insufficient chemical assistance, etc.; but in spite of these difficulties substantial progress has been made and certain provisional conclusions of general interest have been reached. Special attention may especially be directed to the various devices adopted to save labour and simplify the laborious business of selection. Arising out of this aspect of the subject, the possible correlation of morphological characters with richness of juice has been specially studied, and already Dr. Barber is able to say that "from this study it would appear that the seedlings in any general collection, with higher sucrose content, would be marked out by rather narrow, short leaves, but with a relatively high leaf module, with canes that might be thick or thin, but with a leaning towards the thin side, rather long, but not very, and with a moderately high cane module." To this rule there are, however, many and notable exceptions, particularly in the case of definite crosses. It is clear from Dr. Barber's memoir that the initial difficulties experienced at Coimbatore have been successfully overcome to a considerable extent, and the results obtained in the next few years should be of great value to the Indian sugar-cane industry, which has a great deal of leeway to make up before it reaches the level attained in other tropical sugar-producing countries, both on the scientific and the manufacturing sides.

IN a paper read before the Franklin Institute in April Mr. C. J. Gadd, chief engineer of the American Iron and Steel Manufacturing Company, directed attention to the progress which has been made recently in the application of powdered coal to the heating of furnaces for metallurgical and other purposes. If slack coal is dried, pulverised until 83 per cent. of it will pass through a sieve with 200 meshes to the inch, and delivered to the furnace in this finely divided state, its combustion is completed while it is still in suspension, and as high a temperature is attained as with producer gas. From the experience gained with the apparatus used by the American company Mr. Gadd concludes that on further development powdered coal will entirely displace oil, tar, and producer gas in the fields in which they are now supreme. The paper is reproduced in the September number of the Journal of the Franklin Institute.

SOME definite evidence regarding the cause of the accident at the new Quebec Bridge on September 11 has now reached this country, and is dealt with at considerable length by *Engineering* and the *Engineer* for October 13. The accident occurred while the central span was being raised into position, and the whole of this heavy portion of the structure fell into the river. Facilities were given to the representatives of the *Engineering News* to inspect the parts which failed, and from their report it appears that one of the four rocker bearings which supported the central span whilst in course of construction gave way when the span had been raised about 30 ft. *Engineering* hesitates to criticise, since the St. Lawrence Company had sought the advice of many able engineers, but at the same time considers that the design of the rocker bearings was very unsatisfactory in view of the immense load of 1300 tons to be imposed on each. So soon as the span was lifted there was no longer any

## OUR ASTRONOMICAL COLUMN.

FIREBALL OF OCTOBER 3.—A large number of additional observations have come to hand, and Mr. Denning writes us that the brilliant object was well observed as far north as Huddersfield and as far east as Hertford. Even at Huddersfield, where the observer was about 210 miles distant from the object, it exhibited a Venus-like lustre, and was followed until it disappeared in the mist very near the S.S.W. horizon. The new observations confirm, in general, the deductions already stated as regards the position and height of the fireball; but the exact place of the radiant point remains a little doubtful. With reference to the elevation at disappearance, this may have been less than thirty miles, for there are several observations indicating it at about twenty-four miles. The cloudy or misty condition of the sky at many places, however, hindered efforts at exact observation. Everywhere the spectators speak of the astonishing brilliancy of the object and admit that its startling aspect at first aroused fears of a calamitous sequel.

*Erratum.*—By a clerical error Launceston was mentioned instead of Seaton, East Devon, in NATURE, October 12, p. 116.

ANOMALOUS DISPERSION IN THE SUN.—The search for evidence of anomalous dispersion in the sun continues to attract considerable attention. Dr. Albrecht recently concluded that Rowland's measurements gave distinct indications of a mutual repulsion in close pairs of lines, such as is required by the anomalous dispersion theory. Mr. Evershed and Dr. Royds, however, have questioned the validity of this result, since it is not supported by data obtained at Kodaikanal by more direct methods (the *Observatory*, October, 1916). In agreement with Dr. St. John, Mr. Evershed finds that Rowland's separations were almost invariably overestimated; for eighteen pairs having a mean separation of 0·1920 according to Rowland, the Kodaikanal mean value was 0·1836. The tendency of Rowland was therefore to displace the violet components to the violet, and the red components to the red, thus simulating the effects of anomalous dispersion. Mr. Evershed considers that his results are decidedly against the view that anomalous dispersion is an effective agent in displacing solar lines.

Dr. St. John has also made an exhaustive examination of the cases included in Albrecht's list, and is strongly of opinion that the deviations are merely due to systematic errors in Rowland's measures of close lines (Proc. Nat. Acad. Sci., vol. ii., p. 458). He finds that the separations of pairs in the solar spectrum are identical with those obtained from terrestrial sources. "Within the limits of error, evidence of mutual influence is absent from the solar spectrum, and in so far as mutual influence is a necessary corollary of anomalous dispersion in the sun, evidence for it also is absent."

Experimental work bearing upon this question has been carried out at the Pasadena laboratory by Dr. A. S. King (Proc. Nat. Acad. Sci., vol. ii., p. 461). Anomalous dispersion effects in metallic vapours were obtained by the use of the electric furnace, in which a strong density gradient was produced by water-cooling the upper part of the tube. Tests for the mutual influence of lines were made on the mixed vapours of titanium, calcium, and chromium, in which certain lines of the two former elements fall well within the curved spectra given by the anomalous dispersion of chromium lines. When compared with the corresponding emission spectra of the mixture, and of the elements separately, the measures gave no evidence whatever of a mutual repulsion between close lines when anomalous dispersion is active.

THE VARIABLE STAR SZ CYGNI.—Extensive observations of SZ Cygni, covering the period from November, 1912, to August, 1916, have been made by F. C. Leonard (Mon. Reg. Soc. Prac. Astr., vol. viii., No. 5). The star is of the δ Cephei class, having a mean magnitude of 8·96 at maximum and 9·74 at minimum. The mean period is 15·10 days, with an interval of 6·6 days from minimum to maximum. Both range and period appear to be subject to slight variations. The star is stated to be of a reddish tinge, and to deepen in colour as the brightness diminishes.

## FISHERIES INVESTIGATIONS AND DEVELOPMENT.

THE importance of utilising more fully the fisheries around our coasts was emphasised at the recent Newcastle meeting of the British Association, one day being devoted to papers and discussions on this and kindred subjects.

Prof. Herdman urged that with the view of making a rapid recovery from the effects of war, food-producing industries should be encouraged, and, among others, the inshore fisheries should be exploited. Shellfish cultivation, shrimping and prawning, whitebait and sprat fishing, and herring fishing and curing, if extended and exploited judiciously, would add to employment, increase the national food supply, and might lead to the establishment of permanent industries of a profitable nature. He illustrated by several instances how the transplantation of stunted mussels from an overcrowded area to suitable neighbouring areas resulted in the rapid production of mussels of good quality which were sold for eight to ten times the sum expended on their transplantation. As examples of local fisheries started recently, Prof. Herdman mentioned the winter sprat fishery in Morecambe Bay and the summer herring fishery in the Irish Sea.

Prof. Meek gave an account of the inshore fisheries of Northumberland, and pointed out what had been done to preserve them by legislation and to encourage them by such an attempt as that now being made to establish a mussel-bed large enough to supply the wants of the district. The importance to the nation of the fishermen of the smaller fishing stations has been emphasised during the present war. With the problem of the preservation and extension of the coastal fisheries is involved the economic consideration of better buying and selling, and also the social question of making life in the fishing village more attractive.

In his paper on the further development of the shell-fisheries Dr. James Johnstone dealt especially with the coasts of Lancashire, Cheshire, and North Wales, where such fisheries are of considerable actual value and of very great potential value. Here mussels and cockles exist in incredible abundance, though in certain areas a considerable proportion are always smaller than the specified legal size. Mussels are found to prefer shallow estuarine water of low salinity containing the drainage from cultivated land or from human communities. Dr. Johnstone dealt with the rationale of successful transplantation, and calculated that the yield in assimilable food substance of high nutritive value of a cultivated mussel-bed was probably greater than that of a similar area of land bearing a food crop. He pointed out that although mussels feed on contaminated material they can be cleansed, and regarded as pure, by placing them in an area where water coming in from the sea washes over them during the last hour of flood-tide for two to four days. Although it is practicable to develop the yield of the shell-fisheries to an enormous extent, it is difficult to see how this can be brought about without some

Digitized by Google

measure of State organisation for redepositing and cleaning the shell-fish. Dr. Johnstone considered briefly some of the administrative problems involved.

Dr. A. T. Masterman stated that in running sterile water mussels will, in three hours, cleanse themselves of sewage organisms which have been introduced into their mantle cavity and alimentary canal with food. Mussels may be relied upon to feed at night and at a suitably low temperature. It was found that chlorine in any form was not available as a direct sterilising agent, for its presence in the water in any appreciable quantity (0·5 per million) interfered with the normal functions of the mussel, and retarded the self-cleansing processes. Efficient sterilisation of sea-water can, however, be produced by the use of chlorine, and the following process of mussel purification has been devised at Conway by the Board of Agriculture and Fisheries. Into an upper tank river-water (80,000 gallons) is pumped and allowed to settle, and the clean water is run into a lower tank, together with sufficient hypochlorite solution to produce an initial strength of three parts per million. Sterilisation of the water is effected overnight. In other still lower, shallow tanks mussels, which have been thoroughly washed, scoured, and picked over, are placed two deep on grids. The sterile water is then passed into the mussel tanks, its surplus of hypochlorite being removed during its passage by addition of sodium thiosulphate. The mussels remain in the sterile water for at least one night, and are then washed and hosed. They are left in sterile water for another night, and are then ready for packing.

Dr. E. J. Allen referred to the account given by Prof. Herdman of the establishment of a fishery for sprats on the Lancashire coast, and expressed the hope that attempts would be made to establish in this country an industry for preserving these fish in oil, as had been done on a large scale in Norway. He thought that a great deal more might be done in the way of preserving fish if the matter were properly organised. There were often gluts, when large quantities of fish were wasted which might well be saved and made available as food.

In his account of the scales of fishes and their value as an aid to investigation Prof. Meek pointed out that it had been established by a wealth of observations that the physiological processes in fishes suffer a relapse in winter, and that the seasonal diminution in the rate of growth is recorded on the scales, as in other skeletal structures. This discovery has enabled investigators to state the rate of growth, the age-composition of samples, and other important correlated facts. The method was illustrated by photographs of the scales of the herring, bass, and several Gadoids and Pleuronectids.

Dr. Masterman stated that although the great majority of scales in a Gadoid fish, *e.g.* the haddock, show the same number of annual rings, it was possible to find a certain percentage with a smaller or greater number. In large samples of haddock from the Dogger Bank and other parts of the North Sea the scales showed evidence of active growth for two separate periods of the year, the explanation of which is obscure. In the salmon the determination of age is complicated by cessation of growth at certain periods, and also by destruction of the edge of the scale at spawning. As a general rule, the zones on the scales of fishes are an expression of variations in growth dependent upon seasonal changes, but the interpretation of individual cases is full of pitfalls.

Plymouth in December, appear to be heavier in those years in which the sea-temperature is below the normal, but are also dependent in some way upon the preceding summer maximum. During the years 1904–11 (inclusive) the landings of mackerel, which are caught chiefly in May, seem to be correlated with the sea-temperature of that month. For the years 1905–10 (inclusive) the yields of the pilchard fishery fluctuated in the same manner as the magnitude of the seasonal salinity ranges. These are probable measures of the strength of the Atlantic current, which was therefore stronger in those seasons which were followed by a more successful pilchard fishery.

## *BITTER PIT.*[1]

THE disease of apples (and pears) known as bitter pit manifests itself externally by depressions of the surface of the fruit and internally by patches of discoloured and dead tissue. It is a disease which may make its appearance whilst the fruit still hangs on the tree, or it may declare itself in the fruit-room and even in cold storage.

This disease has been, and still is, the cause of great loss to growers. Thus it has happened not infrequently that whole consignments of apples shipped from Australia to England have developed the disease so severely as to have become unsaleable. Hence it is not surprising that so progressive a community as the Commonwealth of Australia should have instituted, with the co-operation of the State Governments, a special research into the nature of the disease, its remedy and prevention. This research, endowed for a period of four years, was entrusted to Prof. D. McAlpine, and the fourth and final report now issued testifies to the assiduity and thoroughness with which both Prof. McAlpine and his colleagues have prosecuted their inquiries. As is pointed out in the introduction to the report, when the investigations which it summarises were begun bitter pit was regarded as a mysterious disease. It is associated with the presence of no parasite, nor is it a consequence of puncture by insects of the skin of the fruit. Ewert had, it is true, advanced evidence in support of the view that bitter pit is a result of the local toxic action of copper-containing spray fluids. That hypothesis has not, however, met with general acceptance.

Our knowledge of the ætiology of this disease being so vague, we turn with interest and curiosity to learn the results of Prof. McAlpine's inquiries; but it must be confessed that although we discover much valuable and interesting information in this large and admirably illustrated volume, we fail to find the revelation of the mystery. The symptoms of the disease are described in detail; evidence is brought forward that severely pruned trees yield more pitted fruit than is produced by lightly pruned trees; that nitrogenous manures appear, albeit often to no considerable degree, to increase the pitting of fruit; that certain varieties are more resistant and certain others more susceptible to the disease—in fine, we learn much that is useful and suggestive, but of the cause or causes of bitter pit we are no wiser after than before the perusal of this monograph. We insist on this point with some emphasis because we think that it should have been made clear at the outset of the report, instead of which we find it there claimed that the research has been brought to a successful issue

Digitized by Google

That Prof. McAlpine has made a definite and valuable contribution to our knowledge of this pathological problem will appear presently, but this is only an added reason why he would have done well to make it perfectly clear that the main problem still remains to be resolved. To conclude that the "immediate cause" of the disease is "the concentration of the cell sap" (p. 75) is not to discover a cause, but to use words the meaning of which is at least as obscure as the nature of bitter pit. Moreover, if quick-acting nitrogenous manures, which lead to sappy growth, encourage bitter pit, how may that disease be attributed to concentration of sap?

Perhaps the most valuable part of Prof. McAlpine's studies is that which demonstrates the possibility of preventing the outbreak of bitter pit in cold-stored apples. As the result of experiment, he shows that if apples be stored at a temperature of about 30° or 32° F., and if fluctuations beyond these limits be prevented, no bitter pit manifests itself during a period sufficiently prolonged to transport the fruit from Australia to Europe. This is a great gain, and the practical results accruing from it should not only pay for the cost of this elaborate investigation, but encourage the Commonwealth to promote further investigations into the origin of the disease.

A point of some interest on the scientific side of the problem is the fact that starch persists in the broken-down tissue of the pitted region of the apple pulp, whence it is concluded that the incipient but invisible stage of the disease occurs in the pre-ripening phase, or at all events during the phase in which starch gives place to sugar. This is plausible, but the opposite view is not precluded that the starch of the bitter pit arises as a result of a reconversion of sugar. In favour, however, of the view that bitter pit develops, although it is not apparent, at an early stage is the evidence obtained by subjecting suspected apples to X-rays, as a result of which it is claimed, and the claim is supported by photographs, that prospective pit areas appear on the radiographs.

Prof. McAlpine is hopeful that the loss due to bitter pit may be ultimately prevented by breeding pit-resistant varieties. It is a work worth undertaking, but nevertheless is not to be undertaken lightly, for it may prove a long business.

## GEOLOGY AT THE BRITISH ASSOCIATION.

THE president, Prof. W. S. Boulton, delivered his address on Wednesday, September 6, to a good audience, and was followed by Prof. G. A. Lebour, who described the general geology of the rocks round Newcastle.

The Permian formation, which forms such a large part of the surface geology in the neighbourhood, received special treatment at the hands of Dr. D. Woolacott, who has made it a detailed study, and brought order out of the complicated bedding He shows that the Middle Permian Beds consist of a fossiliferous, unbedded reef formation, which ran parallel to the coast of the Permian sea, and on each side of which are well-stratified, unfossiliferous limestones, which were formed in waters permeated with calcium sulphate, which afterwards formed gypsum beds. The concretionary formations found in the various beds were lucidly dealt with.

During the meeting Dr. Woolacott took the geologists to see several typical sections of the Permian beds, and exhibited interesting evidence in proof of his contentions.

The important questions of the underground mapping of prominent coal seams were dealt with by Mr. Wickham King in his plexographic model of the South Staffordshire thick seam, by Dr. G. Hickling in diagrams of the Black Mine coal of Lancashire, and by Prof. W. G. Fearnsides in maps of the Barnsley Bed.

In the afternoon a special joint meeting with Section K was held to receive the report of the Research Committee appointed to investigate the Old Red Sandstone of Rhynie, Aberdeenshire, and to hear a paper by Dr. R. Kidston and Prof. W. H. Lang describing the very interesting fossil remains found in that deposit. The present paper dealt only with one of these, *Rhynia gwynne-vaughani*, which is the oldest known peat. The plants, which were rootless and leafless, and grew crowded together, consisted entirely of a system of cylindrical stems, attaining a height of 8 in. or more, and ranging in diameter from 1 to 6 mm. The stems bore small hemispherical projections, from some of which lateral branches were developed. The aerial stems had a thick-walled epidermis with stomata, a cortex, and a simple central cylinder. Large cylindrical sporangia, containing numerous spores, were found in the peat. They were evidently borne terminally on some of the leafless aerial stems.

On Thursday there was an important joint discussion with the members of Section B, which dealt with the investigation of the constitution and classification of coal. A combined geological and chemical study was recognised by all speakers as an essential to success. There was also general agreement as to the need for more systematic and careful selection of samples, for the separate investigation of the various constituent elements of seams, and for the microscopic examination of the specimens analysed. The great national importance of the work was also emphasised. The discussion was opened by Prof. G. A. Lebour, followed by Prof. W. A. Bone, Prof. P. F. Kendall, Prof. P. P. Bedson, Dr. J. T. Dunn, Mr. D. Trevor Jones, Dr. Marie C. Stopes, Dr. G. Hickling, Prof. W. G. Fearnsides, and Prof. W. Boyd Dawkins.

At the close of the discussion Dr. J. W. Evans gave a suggestive description of a method of representing geological formations and structures in black and white on maps. Mr. Leonard Hawkes described the Tertiary acid volcanic rocks of Iceland. In places this acid series is at least 2000 ft. in thickness, and consists of tuffs, sphæro-like liparites, and obsidians, The eruptions were similar to those of post-Glacial times. The uneroded character of the liparite lavas shows how rapidly the successive basalts which submerged them were poured out. Since the close of the Tertiary volcanic period enormous denudation has obtained, and the varying resistance offered to erosive agents by acid and basic rocks has produced remarkable topographical effects.

Dr. Alexander Scott gave the results of an extensive examination of the Arran pitchstones, describing four groups varying from non-porphyritic glasses with abundant microlites of hornblende, to a more basic type with scarce phenocrysts, but with abundance of pyroxene microlites. An attempt had been made to determine the cooling histories from an examination of the field relations and the microscopic structures of the various types, and also to indicate the conditions which were responsible for such a large development of glassy intrusive rocks.

On Friday a joint meeting was held with Section E, to hear a paper by Dr. Albert Wilmore on the Northern Pennines. The structure of the range and its gaps with the intervening rock-blocks were described. The effects of the fault and fold systems on the scenery were dealt with, and many interesting problems which still leave scope for careful investigation were pointed out.

Digitized by Google

A paper was contributed by Prof. W. G. Fearnsides and Dr. P. G. H. Boswell on the occurrence of refractory sands and associated materials in hollows in the surface of the Mountain Limestone district of Derbyshire and Staffordshire. Then Dr. P. G. H. Boswell dealt with the geological characters of sands used in glass manufacture, which gave interesting and important glimpses of the new efforts being put forward to supply our present economic necessities. The report of the committee appointed to investigate the flora of the Lower Carboniferous Beds of Gullane described the finding of a petrified flora in 1914, the most important form of which was Pilys. Many examples of this fossil plant were found, some with bark, and one, a branch tip, still clothed with needle-like leaves. These enabled the connection between leaf and stem to be determined, and much light had been thrown on the stem-structure of the genus. The whole assemblage of plant types exhibited a close similarity with the flora of the Pettycur Limestone in Fife. W. L. C.

### SECTION F.

#### ECONOMIC SCIENCE AND STATISTICS.

OPENING ADDRESS (ABRIDGED) BY PROF. A. W. KIRKALDY, M.A., B.LITT., M.COM., PRESIDENT OF THE SECTION.

*The Need for National Organisation.*

As the war developed there has been a growing tendency to demand organisation in every sphere of national life. The striking successes scored by Germany have been universally, and probably rightly, ascribed to thoroughness of organisation and complete preparedness before provoking the conflict. As a consequence, a comparison has been made between English and German military policy, greatly to the detriment of the former. And, not content with this, further comparisons have been made, with the result that, if one believed all that was printed in the newspapers or accepted what passes in private conversation, we should be led to believe that rule of thumb has been the leading British characteristic. It has been forgotten that Germany has for many decades prided herself on her Army, even as England has relied on her Navy. One has been a great military Power; the other equally great at sea. The test of war has proved that Germany was a very difficult country to oppose by land, but that in naval matters England is supreme. The economist, however, has to go further and investigate into those matters which are connected with his science—namely, the production, the distribution, and the consumption of wealth. Can it be said that the want of organisation and other faults of our military system are typical of what has been going on in the industrial and commercial sphere? I for one cannot bring myself to accept the truth of this. Had our economic interests been carried on under so-called War Office principles we could not have built up the great position we occupy as world traders. What, then, are the facts? To answer this question one should remember the leading facts connected with more recent. She was able to benefit by our experience, nor was she slow in doing so. The agitation for Tariff Reform and Colonial Preferences is a proof that several years before the war broke out some Englishmen were awake to the fact that a new condition had come into existence, and that, if we were to preserve our advantageous position, we must take careful stock of newly arisen factors in world-trade. For Germany was not the only one, nor perhaps the most serious, of these factors. The United States of America, from the time of the Civil War, had bent her energies to the work of internal development. Having concentrated on this for nearly forty years, she began to expand a world-policy, both political and commercial. Japan, too, emerged with unexpected suddenness into the arena. Thus, as the nineteenth century drew to a close, the economic interests of England required careful and earnest attention. The fiscal controversy undoubtedly had the great and important effect of waking English traders out of the lotus-eating condition into which they were in danger of sinking. All our principal, and many of our less important, industries were carefully reviewed, with results that can be realised by a study of the annual statistics published by the Board of Trade. There was, however, a very subtle policy being pursued, which required very minute knowledge and wide experience to grasp. It was our proud boast that we left trade free and untrammelled, that we believed in the health-giving effects of open competition. It needed the stern lesson of the war to make known how this generous policy could be utilised to our detriment by a rival commercial nation. The facts as to the exploiting of the mineral resources of the Empire, as to how the dye and colour industry and various by-product industries have been developed so that certain vital trades almost passed under foreign control, came to light only just in time.

It became plain, as these facts leaked out, that we needed a better system of industrial and commercial intelligence. There was also a lack of unity of working among our principal industries incompatible with the growing interdependence which has been a marked feature of modern economic life.

Hitherto, apparently, it has been no one's business to survey comprehensively the resources whence our raw materials are drawn. Even those resources within the Empire have been nervelessly left to be exploited by the first-comer, and the mask of an English name has enabled foreign capital and energy to divert some of our valuable minerals to foreign countries, whence we have been compelled to purchase them at unnaturally enhanced prices. Sufficient of the facts have been made public to warrant the demand for reconstruction and improved organisation of those departments responsible for the national trade.

It would be most unwise as well as ungenerous to attempt to blame our Board of Trade. That department has, on the whole, worked hard and well for British interests. But it is both wise and necessary to criticise the policy that has overweighted this one Government department. And although there should be very careful consideration before either recommending or making a drastic change, attention ought to be given to the frequently expressed opinions of both chambers of commerce and individual traders in

Digitized by Google

*Industrial Organisation.*

The organisation that has grown up with the development of our industries includes two very important but unequally developed sets of organisation. The industrial army of labour force of this country includes all those who either organise industry or take any part, however important or however humble, in its working. From the captain of industry, or *entrepreneur,* as our brave Allies call him, down to the humblest weekly wage-earner, we have a labour force which ought to be looked upon as one and indivisible. In connection with this force we now have two sets of organisations the interests of which some people consider to be antagonistic. I would emphasise the fact that these two are really one force, their main interests are identical, and they can best serve these interests by striving to minimise differences and by doing all that is possible to work in harmony.

Though theoretically one, the labour force has internally developed two sets of organisations. Manual labour has its trade unions; the organisers of industry have their associations; British trade unions have a fairly long history behind them, and may be said to be in advance of any similar unions the world over. But the fact that of recent years there has been a tendency for small unofficial sections of given unions to kick over the traces and disregard the policy and agreements of their leaders shows that perfection of organisation has by no means been attained.

Employers' associations are of more recent formation, nor have they so far attained to anything like the same completeness. Both organisations, especially the employers', are in need of further development. It is scarcely for the economist to show how this can be effected. He can point to imperfections and make suggestions—only those conversant with practical working facts can formulate a practical policy. The most patent defects of these associations are due to the very virtues of their members. The individual British business man is unexcelled by the business man of any other country. In times of rapid transition and crisis he has again and again shown his leadership. He knows his business thoroughly, and as a working unit he has taken a very high place. But one of the most marked developments of modern trade is a growing interdependence of industries. Hand in hand with this we have become familiar with another phenomenon, the amalgamation of businesses of various dimensions into one great company or corporation. This phenomenon is common to both commercial and manufacturing interests. It is as marked among banks as among steel and iron companies. The comparatively small manufacturer or business man is giving place to bigger and inclusive organisations. These two and somewhat parallel developments are making a new demand on the individual. He and his predecessors exemplified individualism; the new stage upon which we have entered demands a modification of the old policy. Business, like everything else, is subject to evolution, and evolution on healthy lines can only be obtained by grasping fundamental facts and applying experience in accordance with economic laws. There need be nothing revolutionary moment. As a race we are healthily conservative without being reactionary. That is to say, we know how to preserve what is good in the old and amalgamate it with the new. In other words, our organisation enjoys that useful quality of elasticity which enables us to keep abreast of the times.

Bearing this in mind, where are the defects of our business man, and to what does he need to give attention in order to come into line with the most recent requirements?

As I have just said, our business man's qualities emphasise his defects. For generations our business men have worked as units, and individualism has become almost second nature. The call now is that the individual shall sink a part of his personality and become, so far as one side of his activities is concerned, a member of an association. We have had employers' alliances, federations, and associations. Some have failed, some have managed to keep afloat, others have had a certain amount of success. None have hitherto quite attained to what is required. To the onlooker it would appear that when our employers meet as an association there is a lack of sympathy among the members, and if this should persist it would be fatal. Each individual knows his own business; he does not know, and perhaps it would be true to say he does not care to know, his neighbour's concerns. At any rate, as a result there is a lack of cohesion, there is a lack, too, of that co-operation which is required if the association is to be really successful and accomplish the objects for which it has been formed. This working in co-operation, the large organisations of capital, and the working together in associations, are comparatively new things to our business community. Time and experience will put things right; at present we have not accustomed ourselves to a newly developing condition of affairs. Our business men, then, need to focus their attention on these early ailments of the movement and get them removed as soon as possible.

A second group of defects arises indirectly but almost inevitably from that which has just been considered. Some alliances, rings, and associations have failed and come to an end. And in certain cases the cause has been unmistakable, for there has been a lamentable want of loyalty, and even in some cases it must be said honesty, to the agreements entered into by the association.

Only to mention one group as an instance of this—the New Trades Combination Movement, which caused quite a considerable stir during the late 'nineties of last century, especially in the Midlands, among the metal trades. Articles appeared in the journals, and a book[1] was written explaining the movement and great hopes were entertained that a new era had opened out before both Capital and Labour. But all ended in a failure. There was for a time a kind of Syndicalism—a syndicated industry enabling employers to increase their profits, and the workpeople to earn abnormally high wages. So long as competition could be kept out of the market, things went swimmingly and a specious prosperity developed. But the consumer was being exploited—the increased prices charged for such goods as metal bedsteads gave

Digitized by Google

Its cardinal facts should be known to those who now have an opportunity for shaping the industrial future of this country.

Three lessons stand out from this experience:—

(1) We must learn to work together in association.

(2) All members of an association must be absolutely loyal and honest to their engagements, either written or implied.

(3) Such associations must be regulated or the community will be exploited.

Nor is it impossible to suggest a method by means of which this may result. When employers' associations have justified themselves it should be possible to obtain State recognition for them, and it would be practical politics, when both employers' associations and trade unions have developed to the point at which both merit State recognition, to enforce under penalty agreements made between them on all those, either employers or workpeople, who wished to work at the industry within the area under the recognised organisations. Thus it would not be necessary to make membership compulsory; self-interest would be the extent of the pressure.

Turning to workpeople's unions, we also find defects which require removing. The policy of union has been practised among the workers for upwards of a century, and for at least half that time with well-marked success in certain directions. In the first instance it was the aristocracy of labour that realised the advantage of collective action, but, notably since the late 'eighties of last century, efforts have been made to extend the policy to all grades of labour. Hence the ailments which have to be noted are rather more mature than those affecting employers' associations. Success in certain directions has perhaps led some of the more ardent spirits to expect more from their unions than working conditions allow. The experience of old and tried leaders has led them to adopt a more cautious policy than the young bloods are inclined to accept. Hence there has been a want of loyalty, different, it is true, from that met with among employers, but equally disastrous if persisted in to the object in view.

All the men in a given industry should be members of the union, provided that the union is well organised and ably administered. This should, however, be the result of self-interest and a regard for the good of fellow-workers, rather than of compulsion; how that may be attained has been suggested. Perfection of organisation will come when workpeople not only realise the real possibilities of collective action, but are prepared to follow loyally leaders who have been constitutionally elected. The leaders are in a better position to know the facts of the case immediately under review, but if their leadership has been found faulty there should be adequate machinery for replacing them with men who command the confidence of the majority of the members. When agreements have been entered into, the terms should be implicitly observed, even though they may turn out to be less advantageous than was expected. Periodical revision would make it possible to rectify mistakes or misapprehensions. But it cannot be too strongly emphasised that for both sets of organisation the great factor making for smooth and satisfactory working is absolute loyalty to the pledged word. A large employer of skilled labour writing to me on this point said:—"In my opinion no industrial harmony can exist between employers and employees until trade unions through their executives can compel their members to adhere to and honourably carry out all agreements entered into with the employers. . . . In fact, until a more honest code of morals exists on both sides no improvement can be looked for."

Further, there is a need for a more complete and authoritative central authority, both for individual industries and for federated trades. The machinery for this exists, it merely requires development. When the local and central machinery has been perfected, the right to *strike*, which, in common with the right to *lock out* as a final resource, should be jealously maintained, would be carefully regulated, and would only be resorted to as the considered judgment of the most experienced men on either side. It should be impossible for either an individual association or a section of it to order a strike or a lock-out on its own responsibility.

What, then, do I consider should be the main outline of industrial organisation? Employers should be organised into:—

(*a*) Associations of one trade in a given district.
(*b*) National associations of one trade.
(*c*) Local federations of trades.
(*d*) National federations of trades.

Of these, (*b*) and (*d*) should be organised under a system of representation.

Workpeople should have unions and federations corresponding to those of the employers, and in both cases the national federations should be carefully organised councils, who would enjoy a large measure of authority, tempered by the necessity to win and preserve the confidence of their electors. From these two representative bodies there could be elected an industrial council as a court of appeal, representative of the whole industrial activity of the country, and so far as these various bodies were approved by the State they would enjoy far-reaching powers.

Approval by the State should depend on the observance of moderation and working in conformity with carefully devised regulations. For the State in this matter would be the representative of the consumer and of the national interest. Without this you get something not very far removed from Syndicalism, but under careful regulation abuses might be avoided.

At the head of the organisation there would be a real industrial council representing the industry of the country. The industrial council established in the year 1911 has never had a fair chance to show its mettle. It was established at a critical time; perhaps the Government did not feel justified in throwing a great responsibility on an untried body. Nevertheless, it exemplified a very wise policy, and one regrets that it has not been tested, for even now both employers and workpeople feel that some such council is preferable to State interference, and there is a clearly articulated distrust on both sides of official arbitration.

We do not need at the present juncture to attempt a new experiment. Our old system, whatever its failings, has been tried and proved sound. Its elasticity has been its salvation, and it is capable of still further evolution without calling for drastic changes. The improved organisation that is now suggested would contain nothing that is new or untried. It would consist of natural developments of what already exists. Employers and workpeople have organised themselves into associations and unions, some of these have developed federations of similar or even of unconnected interests; and both parties have their national congresses, or at any rate the germ of them. The demand now is that the organisations already in existence be perfected, and that those perfected organisations shall in all their agreements be loyally and honestly supported by their members. Success depends on absolute loyalty to the pledged word.

Here we have a practical policy suited to the needs of this critical stage in our history. The ideal organisation has yet to be formulated, but what is here proposed would form a definite step in advance, and

Digitized by Google

the very elasticity of the system would be a good augury for the future.

A committee of this association has been investigating for the past two years into the extent to which women have recently replaced men in industry. A certain amount of exaggeration exists as to the number of women who have entered our factories or undertaken services left vacant by men who have joined the Forces. The total number is, in round figures, about 600,000, as against five million men who have joined either the Navy or the Army as a consequence of the war.

The entry of large numbers of women into industry has been viewed with a certain amount of alarm by the men; and trade unions have naturally stipulated, where possible, that these women shall receive the same rates of pay for the same work as the men, and that when the men return the women shall give place to them.

That there was little ground for alarm as to the influx of women can be realised by a consideration of a few facts and figures. The majority of men who enlisted were workpeople of one sort or another; of these, unhappily, some have been killed in battle or have been rendered incapable for work. Even so, the majority will come home requiring occupation. What opportunities will they find?

To answer this question at all satisfactorily it is necessary to consider some determining factors. Thousands of men have left indoor occupations and their accustomed town life and have been trained, drilled, and disciplined under open-air conditions. They have lived, worked, and fought in the open country in some cases for many months. The new experience has had potent effects. Physique has improved, the outlook on life has changed, in many cases new hopes for the future have been formed. Inquiry shows that there is a division of opinion as to the extent to which disbanded members of the Forces will decide on making a radical change in their mode of life. Yet the experience of what occurred after the South African War warrants us in assuming that considerable numbers will only return to indoor occupations and town life if there be no alternative. It is too soon yet to form an opinion as to what opportunities there will be for land settlement. But it is known that offers will be made, both at home and in various parts of the Empire. A moderate estimate of those accepting these offers, and of our losses of killed and permanently disabled, would be at least one million. Then we shall undoubtedly require, at any rate for some years, a much larger standing Army. Even on a peace footing this at a moderate computation may be put at a million men. These two figures, and neither of them errs on the side of exaggeration, will absorb two million men who will be permanently lost to the old occupations.

Moreover, there is good ground for anticipating that if the war concludes before our resources are unduly strained, and there is every prospect that it will, there will be a period of good trade. We have to restore our own depleted stocks of goods, our mercantile marine demands a large amount of new tonnage, railways and other transport services will require renewal, but our man force has been greatly improved, and our industrial equipment to a great extent remodelled.

Reverting to the somewhat thorny question of the women who have been engaged on what were men's occupations, I see no cause for alarm. Many women came forward from motives of patriotism, and will gladly resume their former state. The question, I believe, will rather be how can we obtain the labour necessary to cope with the post-war demand.

The new equipment of our factories will place us in a position to increase very greatly our ouput, and this should enable us not only to face a possible labour shortage, but if the recommendations made by this section of the association meet with a favourable response, our labour force should enter upon a new period of prosperity consequent on a remodelling which has been rendered possible by a reorganisation of our industrial machinery. This new epoch for labour would include higher wages, shorter hours, and better working conditions. To effect these salutary advances both employers and employed need to exercise sanity of judgment, frankness in mutual discussions, and a recognition of the fact that the prosperity and material well-being of each is bound up in a common effort to maintain and develop our industrial and commercial position.

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The term has opened with a greatly reduced number of undergraduates. Exact figures are not yet forthcoming, but they will certainly be small. The current issue of the *University Gazette* contains the names of 312 members of the University who have lost their lives on active service during the last three months, all but a very few having been killed in action. The usual lists of lectures, demonstrations, and laboratory work have been issued by the heads of the various science departments. The programme published by the School of Geography includes lectures by the acting director on geographical method and on the distribution and economic geography of primitive societies; by the demonstrator, on regional geography of the British Isles; and by Messrs. Spicer and Kendrew, on land forms and climate. Practical classes will also be held. The Committee for Anthropology has arranged for lectures on physical anthropology, ethnology, theories of totemism, and primitive archæology. These will be given by Prof. A. Thomson, Miss Czaplicka, Mr. H. Balfour, and Dr. Marett. Demonstrations and informal instruction on a large variety of subjects connected with anthropology are also announced.

---

THE widow of Prof. Gwynne Vaughan has presented to the Botanical Department of the University of Glasgow the collection of more than 2000 slides, in mahogany cabinet, belonging to her late husband, and the originals of all his published memoirs.

A SPECIAL course of short lectures is to be given by Mr. E. F. Etchells to the Junior Institution of Engineers on alternate Friday evenings, beginning

Digitized by Google

common standard for entrance to the separate universities. The various universities are represented on the board, and about five practical teachers are co-opted, so that the schools and universities are kept in touch with one another. According to the *Morning Post* of October 13, Birmingham University is to be included in the operations of the board, and thus another step is taken in the direction of securing a uniform standard for entrance to a university. We also learn from our contemporary that the Vice-Chancellor of Liverpool University, who is the chairman of the Joint Board, stated at a special meeting of the Liverpool University Court on October 12 that the University authorities at Bristol proposed recently that the Bristol University should be included in the scheme, but a final decision had been postponed until after the war.

AN address by Sir Henry A. Miers on "The Place of Science in Education" is printed in *Education* for September 15. In outline the views expressed may be summarised as follows:—In elementary schools science can be little more than common-sense thinking about, and intelligent interest in, the ordinary events of everyday life, the main aim being to encourage a feeling of the necessity for personal trial and effort in understanding what is seen and done. In secondary schools there should be a systematic course of experiments, especially in the physics and chemistry of ordinary life, in order to encourage a habit of reasoning from what has been observed. This systematic course should be preceded by an introductory course dealing with scientific facts and ideas. All the work here outlined should precede the division of the school into "moderns" and "classics." On the modern side real scientific training is obtained from the laboratory work which becomes essential, but on the classical side science might well deal with general principles through the history of science and discovery, the whole subject being taught in language of a literary character freed from technical phraseology. Such a scheme involves the teaching of general elementary science in the preparatory schools.

IN the *Fortnightly Review* for October the subject of science and the *rôle* to be assigned to it in the curriculum of the higher schools and universities is considered in a suggestive article entitled "Education To-day and To-morrow," by Mr. P. E. Matheson. Reference is made to the manifesto issued a few months ago pleading for a larger infusion of scientific knowledge into the public service, and it is suggested that whilst the critics have made good their complaints of serious defects in our war administration some of the criticisms are to be met by other means than educational reform, as, for example, the conversion of men of business to the belief that scientific research pays. Mr. Matheson admits that unless we have more science in the schools we shall perish. But it is declared that we are up against faults of character and a disbelief in the value of disciplined intelligence. Yet we cannot hope for a cure for these defects either in respect of employers or of persons in the higher service of the State unless it be through the schools and as a result of systematised training, not only in languages, history, literature, and mathematics, but also in the facts and potentialities of scientific knowledge, together with the due training of hand and eye, and accompanied by those formative agencies which promote self-reliance and sterling character. The article is a welcome indication of a more liberal attitude towards the claims of science in the schools and universities.

THE annual congress of the Textile Institute, which met at Leeds on October 13, was in the main concerned with the question of scientific research in the application to the needs of the textile industry. Much has been done of late years in the encouragement of research in the great textile schools of Manchester for cotton goods, and in those of Leeds and Bradford for woollen and other animal fibres, but there is still to lament the indifference of manufacturers to the fruit of such research and to the importance and value of skilled, scientific labour. Dr. Sadler, in welcoming the delegates, pleaded for better appreciation on the part of manufacturers, and for a higher scale of remuneration for those engaged in research in our universities and in the technical colleges attached thereto. When shall we have an English example such as that of the firm of Zeiss, in Jena, which in the course of years has contributed considerably more than 100,000*l.* to the University of Jena as a mark of its appreciation of the value of the scientific assistance it has received therefrom? It is not merely in the adoption of ingenious mechanical contrivances to displace hand labour and so to increase production, the invention of which is shared by the textile-producing nations, but the question goes far deeper than this, in the closer investigation of the fibres with a view to their more successful treatment; in the discovery and scientific manipulation of new fibres, even to the production of artificial fibres; and in the skilful adaptation of material, hitherto regarded as waste, to the production of saleable goods. In the latter aspect of the question the superior chemical training and skill of our foreign competitors on the Continent have enabled them to compete most seriously with important branches of our textile trade, especially in respect of the dyeing and finishing of textile goods. The future of the coal-tar industry was the subject of an address by Prof. A. G. Perkin, who maintained that the production of synthetic dyes, in which Germany had outdistanced this country so completely, was due to the neglect of the manufacturer, the chemist, and of the technical schools. We needed, said Mr. J. H. Lester, of Manchester, a better organisation of industrial education, research and co-operative agencies of all concerned on scientific lines, in order to ensure the maintenance and progress of our industries. There was not, said another speaker, Dr. M. O. Forster, a sufficient supply here of well-educated, clear-brained, intelligent young men of sound character and real perseverance in the chemical world.

THE attention which is being directed to educational topics in the public utterances of men distinguished in various forms of national activity is, it may be hoped, an indication that the importance of a sound and well-balanced system of national education in this country is beginning to be understood. On October 11 Lord Haldane delivered the first of a series of lectures on after-war problems, arranged by a joint committee of Birmingham University and the Workers' Educational Association. He said it was his wish to devote his remaining days to being a missionary on the great question of education. We remember, however, that though, when president of the British Science Guild, he was an advocate of increased attention to education and science by the State, he did little, when he possessed political power, to see that the nation was given the fullest scientific and educational equipment. In his address on October 11 he maintained that what we want is training, and it is the mental training of the future generation that is going to count. When peace comes, he continued, we shall hear no more in Germany about 16-in. guns, but a great deal about continuation schools. The Germans are training up a generation of skilled workmen with whom we cannot compete. We must take care to train the children of our working classes in at least as good a way as the Germans

Digitized by Google

have been able to train theirs. Mr. L. A. Legros also referred to education in his presidential address to the Institution of Automobile Engineers on October 11. Never, he said, in the history of engineering has the ignorance of science by the politicians, the military, and other authorities been so openly displayed as in the early stages of the war, and never has it proved so costly in time, in life, and in material. How many lives and how many millions of pounds, he asked, would the country have been saved if as much study in time and thought had been expended on science as on classics by our law-makers and law-givers? He pleaded that science should be given its proper place in education, and that due care should be exercised in providing suitable training for those women who, as mothers and teachers, would have charge of the earliest training of our future men.

## SOCIETIES AND ACADEMIES.

### PARIS.

**Academy of Sciences**, September 25.—M. Camille Jordan in the chair.—E. **Belot**: The origin of the rotations and revolutions in the forward or backward sense, as well as the origin of cometary orbits.—J. **Guillaume**: Occultations of the Pleiades, observed on September 16, 1916, with the 16-cm. Brünner equatorial of Lyons Observatory.—M. **Boll** and L. **Mallet**: Determination of the practical constants of the Coolidge tube. The Coolidge tube is very stable, and the X-radiation can be maintained for a long time constant, both as regards emissive power and degree of penetration. It is easy to change from hard to soft rays and the reverse. The practical yield is of the same order as other focus tubes for soft rays. The radiation from a Coolidge tube is not appreciably more homogeneous than that of other tubes.—J. **Bougault**: The acidylsemicarbazides. A general account of their physical and chemical properties as a group.—P. **Paris**: *Sphaeromicola topsenti*, a new genus and species of Ostracod.—A. **Lumière**: The comparative action of antiseptics on pus and on pure cultures. The experiments were carried out with three disinfectants of different types—phenol, sodium mercury-phenol-disulphonate, and sodium hypochlorite. These were allowed to act under similar conditions upon the concentrated pus, culture of the pus, and a pure culture of the predominating staphylococcus from the pus, and also upon 1 per cent. dilutions of these. The albuminoid substances present in the pus attenuate slightly the bactericidal effect of phenol; this action is a little more marked with the mercury compound, and becomes very important with the hypochlorite.—R. **Wurtz** and E. **Huon**: The variolisation of heifers immunised against the vaccine.—Em. **Bourquelot** and A. **Aubry**: The biochemical synthesis of α-propyl-*d*-galactoside with the aid of a ferment contained in air-dried low yeast.

# MACMILLAN & CO.'S NEW BOOKS.

## Political Frontiers and Boundary Making.

By Col. Sir THOMAS H. HOLDICH, K.C.M.G., K.C.I.E., C.B., D.Sc., Author of "The Gates of India." 8vo. 10s. net.

*THE TIMES.*—"Sir Thomas Holdich discusses and analyses with great skill and insight the various kinds of artificial frontiers which the world has seen, from the Great Wall of China to the line of entrenchments which marks the limits of German invasion in the West to-day."

*1916 ISSUE NOW READY.*

## The Statesman's Year-Book.

Statistical and Historical Annual of the States of the World for the Year 1916. Edited by J. SCOTT KELTIE, LL.D., assisted by M. EPSTEIN, M.A., Ph.D. With Maps. Crown 8vo. 10s. 6d. net.

VOLUME II. NOW READY.

## The Deposits of the Useful Minerals & Rocks; Their Origin, Form, and Content.

By Dr. F. BEYSCHLAG, Prof. J. H. L. VOGT, and Dr. P. KRUSCH. Translated by S. J. TRUSCOTT, Associate Royal School of Mines, London. Vol. II. LODES—METASOMATIC DEPOSITS—ORE-BEDS—GRAVEL DEPOSITS. With 176 Illustrations. 8vo. 20s. net. Previously published: Vol. I. Ore-Deposits in General—Magmatic Segregations—Contact Deposits—Tin Lodes—Quicksilver Lodes. With 291 Illustrations. 8vo. 18s. net.

*** These two volumes form the complete work on Ore-Deposits.

*ENGINEERING.*—"The literature quoted shows how thorough and exhaustive has been the research, and with what completeness the authors have achieved their task. . . . The authors have been very fortunate in finding a translator so well equipped for the task, at which he has worked with as much success as industry."

## Discovery; or, The Spirit and Service of Science.

By Professor R. A. GREGORY. With 8 Plates. Crown 8vo. 5s. net.

*THE BRITISH MEDICAL JOURNAL.*—"The book is full of human interest and may be read with enjoyment and profit by laymen and scientists alike; it contains a great deal of sound history, and the author shows no little literary skill in his avoidance of the tedious moralizing to which writers on the British apathy to science are so lamentably prone."

PART IV. JUST PUBLISHED. COMPLETE IN 1 VOL. (Pts. I.–IV.) NEARLY READY.

## A Class-Book of Chemistry.

By G. C. DONINGTON, M.A., late Senior Chemistry Master, City of London School, Author of "Practical Exercises in Chemistry." Illustrated. Crown 8vo. Part I. 1s 6d. Parts I. and II. 2s. 6d. Parts II. and III. 2s. 6d. Parts I.–III. 3s. 6d. Part IV. METALS. 2s. Complete in 1 Vol. Pts. I.–IV. 5s.

*NATURE.*—"The earlier parts have rendered useful service to the teaching of elementary chemistry, and the present volume is up to the level of those previously issued."

## A Laboratory Manual of Foods and Cookery.

By EMMA B. MATTESON and ETHEL M. NEWLANDS. Crown 8vo. 6s. 6d. net.

## A Manual of Practical Physics.

By H. E. HADLEY, B.Sc., A.R.C.Sc., Principal of the School of Science, Kidderminster. Illustrated. Globe 8vo. 3s.

*THE SCHOOLMASTER.*—"The help to be derived from such a text-book is incalculable. To the lonely student it will come as a boon. Its exercises are workmanlike and searching, and its 265 pages are cheap at the price."

## A Text-Book of Practical Physics.

By H. S. ALLEN, M.A., D.Sc., Senior Lecturer in Physics, University of London, King's College, and H. MOORE, A.R.C.Sc., B.Sc., Lecturer in Physics, University of London, King's College. Extra crown 8vo. 8s. 6d. net. Also PART I. PROPERTIES OF MATTER. 3s. net. PARTS II., III., and IV. SOUND, LIGHT, AND HEAT. 3s. net. PARTS V. and VI. MAGNETISM AND ELECTRICITY. 3s. net.

*NATURE.*—"The book as a whole is a valuable addition to the list of text-books on practical physics, and the authors show an intimate acquaintance with the difficulties of both students and teachers which should make it very acceptable to both."

PART II. JUST PUBLISHED.

## Practical Mathematics for Technical Students.

Part II. By T. S. USHERWOOD, B.Sc., Wh.Ex., A.M.I.Mech.E., and C. J. A. TRIMBLE, B.A. Crown 8vo. 7s. 6d.

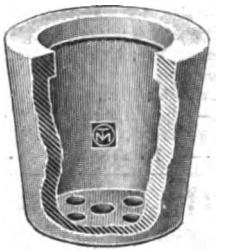
(ENGLAND.)

A GREATLY IMPROVED

LABORATORY SINK PLUG

Regd. No. 630980.



SAVES CHOKING OF WASTE PIPES.

**Simple to fit and easy to remove for cleaning.**

This is a hollow earthenware plug with a perforated base. The top of plug fits just below the level of the bottom of the sink, and any solid matter, such as waste filter paper, broken glass, &c., is caught by it. It can be lifted out for cleaning by means of the flange on its inner edge.

TOWNSON & MERCER. LTD.,

34 CAMOMILE STREET, LONDON, E.C.

PATENT ELECTRICAL RESISTANCE FURNACES.

(Patent No. 10,415, 1914.)

**For Temperatures up to 1000°C. wound nickel chromium wire; above 1000°C. to 1300°C. wound platinum strip.**

Furnaces for the Laboratory built on our patented principle in all Types and Sizes:—

**(1) Vertical and Horizontal Tube Furnaces.**
Specially recommended for Annealing purposes.
**(2) Carius Explosion Furnaces.**
**(3) Multiple Tube Furnaces for the determination of Carbon in Steel.**
**(4) Crucible Furnaces.**
**(5) Muffle Furnaces.**

*ARRANGED FOR ALL VOLTAGES—D.C. or A.C.*

**ADVANTAGES.—Low Cost, Long Life, Low Current Consumption. Can easily be taken to pieces in a few minutes, allowing immediate renewals to be made by the user with repair parts we supply.**

☞ See Editorial Notice, NATURE, Dec. 30, 1915, page 489

# Whatman Filter Papers are British

**TESTS have proved their high quality for careful and accurate work. Use Nos. 1-5 for general filter purposes; the remainder are Acid Extracted Grades.**

**No. 1.**
For general quantitative and qualitative work. Retains Barium Sulphate. Equivalent to C. S. & S. 595.

**No. 2.**
Similar to the No. 1, made slightly heavier. Rapidly filters fine precipitates. Leaves clear, bright filtrate. Equivalent to C. S. & S. 597.

**No. 3.**
A still heavier paper adapted to pressure and vacuum filtration. Filters fairly fast, yet retains fine precipitates. Equivalent to C. S. & S. 598.

**No. 4.**
Very soft, open in texture. Rapidly and perfectly filters fruit juices, syrups, oils, varnishes, etc. Equivalent to C. S. & S. 604.

**No. 5.**
A specially hardened paper of great purity. Very strong; retains finest precipitates. Equivalent to C. S. & S. 602.

**No. 30.**
Hydrochloric acid treated. Low ash, close texture. For quantitative work. Equivalent to DREVERHOFF 207.

**No. 40.**
A paper treated by both Hydrochloric and Hydrofluoric acids. Has less ash than No. 30. For very accurate quantitative work. Retains finest precipitates. Equivalent to C. S. & S. 589 (White Ribbon).

**No. 41.**
Treated same as No. 40, but more open and filters more quickly. Not recommended for filtering very fine precipitates unless properly precipitated. Equivalent to C. S. & S. 589 (Black Ribbon).

**No. 42.**
A new grade, resembling Nos. 40 and 41 in chemical qualities, but differing in its physical properties, being much harder and extremely close in texture. Suitable for use in filter pumps. Equivalent to C. S. & S. 589 (Blue Ribbon).

**Nos. 43, 44 & 50, also Folded Filters & Fat Extraction Thimbles, will be out shortly**

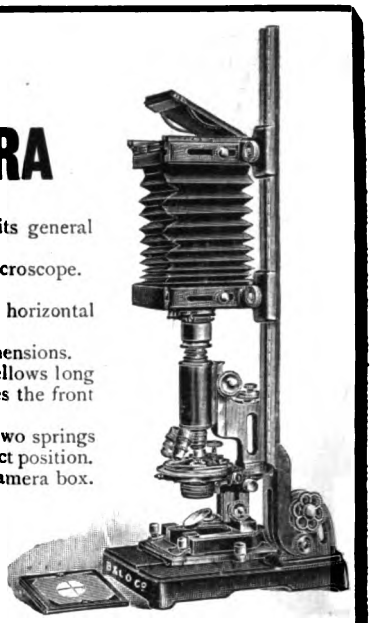
## PHOTOMICROGRAPHIC CAMERA

### Model H



Designed for medium power work in any laboratory, and has long demonstrated its general efficiency and convenience for such purposes. Its features include:—

**Heavy Base,** 13 × 9½ in. **Adjustable Plate,** 8 × 6 in., to carry microscope.

**Graduated Optical Bed,** 25½ in. long, carrying camera parts.

**Inclination Joint,** permitting optical bed to be adjusted at any angle between horizontal and vertical.

**Adjustment of Camera Supports** to align with microscopes of different dimensions.

The two camera-supporting frames are clamped to the optical bed and carry a bellows long enough to accommodate work at any distance along the bed. The first frame carries the front board with tube adapter for the microscope, or a shutter and this adapter.

The rear frame carries a plate-holder box with a hinged cover at the back and two springs permitting the plate-holder to be laid in place and then gently but firmly pressed into exact position. The focussing screen of ground glass with clear centre slides in two grooves in the camera box.

The microscope plate has a movement of 4½ in., permitting the microscope to be removed from the optical centre for examining a slide and quickly replaced. The adjustments on the plate will accommodate **any standard microscope.**

**Price, without Shutter, £9 7 6**

ALSO LARGER MODELS FOR ADVANCED WORK.

Inspection invited at our Showrooms, or List "C-c 1" sent post free.

Also MICROSCOPES for all requirements (over 114,000 sold), MICROTOMES, PROJECTION and DRAWING APPARATUS, CENTRIFUGES, VISCOSIMETERS, etc.

TRADE MARK.

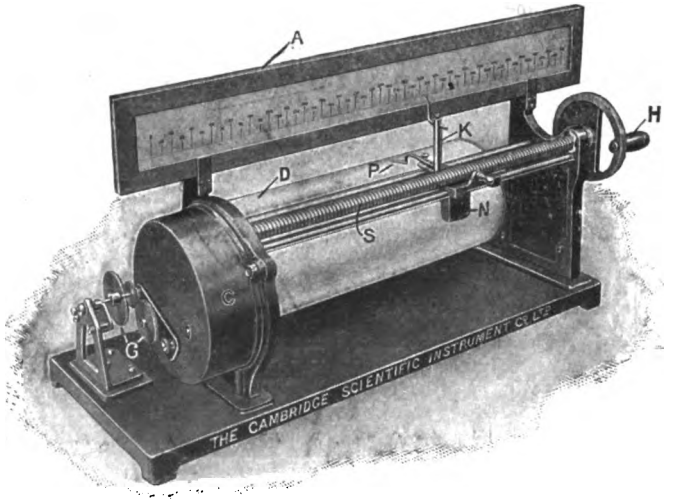
**Bausch & Lomb Optical Co. Ltd.** *Contractors to British, Indian, Colonial and Foreign Governments.*

Agents for BAUSCH & LOMB OPTICAL COMPANY, of ROCHESTER, N.Y., U.S.A.

**37-38 HATTON GARDEN, LONDON, E.C.**

Our Instruments may be obtained through all Dealers.

# THE BREARLEY CURVE TRACER



This apparatus was originally designed for rapidly obtaining

**RECALESCENCE CURVES**

on a very open scale and with rectangular co-ordinates. It may, however, be used to record curves in any experiment in which the deflections of a galvanometer vary with time.

A full description of the apparatus is given in Leaflet No. 132 N, which will be sent on request.

## THE INSTITUTION OF MECHANICAL ENGINEERS.

THOMAS HAWKSLEY LECTURE, 1916.

MR. HARRY E. JONES, *Member*, will deliver the above Lecture on "THE GAS ENGINEER OF THE LAST CENTURY," in the Hall of the Institution of Civil Engineers, Great George Street, Westminster, Friday, November 3, 1916, at 6 p.m.

Visitors invited.

## GEORGE HENRY LEWES STUDENTSHIP IN PHYSIOLOGY.

The Studentship is of the value of £200 a year and is tenable for three years. Its object is to enable promising Students to give their whole time to Physiological Research. It is in the power of the Trustees to elect a second Student. Candidates are requested to send a short statement of their qualifications to Prof. LANGLEY, Physiology School, Cambridge, by November 18.

## SOUTH AFRICAN SCHOOL OF MINES & TECHNOLOGY, JOHANNESBURG

**(Under the University of South Africa Act, 1916, a Constituent College of the University of South Africa).**

The Council of the South African School of Mines and Technology invites applications for the following appointments, viz.:—

Department of English, Logic and Philosophy: PROFESSOR and ASSISTANT.
Department of History: PROFESSOR.
Department of Modern Languages:
(i) Dutch—PROFESSOR.
(ii) French—PROFESSOR.
Department of Classics: PROFESSOR and ASSISTANT.
Department of Education and Psychology: ASSISTANT.
Department of Economics: Commercial Geography—ASSISTANT.
Department of Physics: PROFESSOR and ASSISTANT.
Department of Botany: PROFESSOR.
Department of Zoology: PROFESSOR.

A Three years' contract will be granted in each case.

Salaries: (a) Professors, £800 per annum, rising by annual increments of £50 to £900, and by similar increments to £1000 in the succeeding two years, where the appointment is confirmed and the member placed on the permanent staff; (b) Assistants, £350 per annum, rising by annual increments of £50 to the maximum of £450.

£75 will be allowed to Professors for travelling expenses to South Africa, and £50 to Assistants; half-salary will, in each case, be paid from date of sailing till arrival in Johannesburg.

The next session begins early in March, and the successful applicants will be expected to reach Johannesburg by February 15th, 1917.

The members of the staff have to supervise, and take part in, Evening work.

Applications in triplicate, stating age, professional qualifications and experience, as well as information regarding candidates' publications or researches, should, with copies of three recent testimonials, be sent not later than November 16th, 1916, to the undersigned, who, on application, will send a memorandum containing full information of the above appointments, and of the scheme for the expansion of University education on the Witwatersrand in the immediate future.

Before appointment, the selected applicants will be required to pass a medical examination.

CHALMERS, GUTHRIE & CO., LTD.,
9 IDOL LANE,
LONDON, E.C.

## DERBY EDUCATION COMMITTEE. TECHNICAL COLLEGE.

# THE "GALVANOSET" No. 1

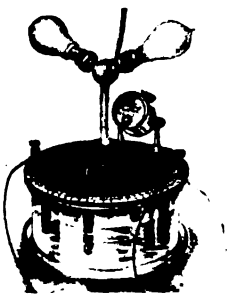
A device for utilising the main supply of electricity, continuous or alternating, of any voltage, for the *immediate* production of low voltage currents from 0·5 to 100 volts such as are required for

**LABORATORY EXPERIMENTS.**

This apparatus has been largely employed by the medical profession for producing the currents that are required for passing through the human body, for which purpose accumulators and dry cells have been hitherto employed.

The apparatus comprises a vessel of water, two fixed electrodes, and two movable electrodes. The main current is connected through two lamp resistances to the movable electrodes, and the circuit of utilisation is connected to the two terminals shown at right and left of the vulcanite top of the vessel.

When the four electrodes are at right angles, *i.e.* at equal distances apart, the potential at the utilisation terminals is zero; when moved a degree from this position, a potential is at once obtained varying in intensity with the amount of displacement. The polarity of the supply can be readily reversed by moving the pointer in the opposite direction. The complete apparatus weighs 7 lb. only. The price of **£8 8 0** includes a moving coil milliampere-meter with shunt winding; if this is not required, the price is only **£6 6 0**



To summarise, the following advantages render the "GALVANOSET" superior to all other methods:—

Nothing to get out of order.
No expense for upkeep.
Always ready for use.
Does not require re-charging.
Nothing to wear out.
Costs less than one farthing per hour to run.
Safe under all circumstances.
Finest range of adjustment.
Any desired current.
Light and portable.

THURSDAY, OCTOBER 26, 1916.

## "METEORITICS."

*Meteorites: their Structure, Composition, and Terrestrial Relations.* By Dr. O. C. Farrington. Pp. x+233. (Chicago: Published by the Author, 1915.) Price 8*s*. 6*d*.

THE treatise on meteorites written by the well-known curator of geology at the Field Museum of Natural History, Chicago, will meet a difficulty that has long faced the student who, while desirous of studying this subject, has hitherto looked round in vain for a comprehensive text-book. Sir L. Fletcher's handbook and guide to the meteorite collection at South Kensington, which is now in its eleventh edition, is admirable so far as it goes; but its scope is naturally limited, since it is intended for the ordinary visitor to the museum. Meunier's "Météorites," which formed part of an "Encyclopédie Chimique," was published so far back as 1884, and is therefore out of date, and probably not now readily accessible. Cohen's "Meteoritenkunde" was excellently planned, but was unfortunately cut short at the end of the third of the five parts in which it was intended to be by the author's death in 1905; indeed, he did not live to see the third part appear.

At the outset Dr. Farrington attempts to solve the problem of finding a name for the subject, and suggests "Meteoritics," a word that seems to serve the purpose very satisfactorily, since "Meteoritology" is ruled out because of the inevitable confusion with that branch of science which is concerned with the weather. Previously "Astrolithology" had been proposed by Shepard, and "Aerolitics" by Story-Maskelyne, but neither word is suitable or suggestive.

The book consists of two parts, though it is not so divided, dealing the one with the mode in which meteorites have reached the earth's surface and their possible origin, and the other with their physical and chemical characters. But for the protection afforded by the atmosphere the fall of a meteorite would not be the comparatively rare phenomenon it is at present. Most of the erratic bodies which meet or overtake the earth are burnt up long before they reach the ground, and the velocity of those that do survive the passage through the air is so reduced by the friction that the rate of fall is only what would be due to gravity had they fallen from heights which have been variously estimated from 4 to 46 kilometres. The disruptive force generated by the heat resulting from the friction causes meteorites to burst into pieces which are often quite small. Nevertheless, some of the masses which must have fallen, though there is no recorded evidence of the fact, have been of considerable size and weight. The largest as yet known is the Ahnighito—one of those located at Cape York, West Greenland, by Admiral (then Lieut.) Peary in 1895, and now in the New York Museum; it weighs 36½ tons. The next in size is that of Bacubirito, Mexico, which, on account of its inaccessibility and the difficulty of transport, still remains where it originally fell; its estimated weight is 27 tons. Pathetic interest attaches to the photograph which is reproduced as a frontispiece. It represents the late Prof. H. A. Ward standing beside the Bacubirito meteorite. An indefatigable collector of meteorites, he was ready to start at a moment's notice to any part of the globe in search of one. He returned in safety from all his expeditions, only to be run over and killed in the street at Rochester, N.Y., where he had his home.

Meteorites are distinguished from terrestrial rocks both by their structure and by their mineral composition. All the elements present in the former are known terrestrially, but some of the common elements, such as barium, strontium, lead, and bismuth, have not been detected in meteorites, at least not in quantity or with certainty. Many of the minerals present in meteorites are peculiar to them, and have not been found terrestrially—for instance, oldhamite (calcium sulphide), schreibersite (iron-nickel-cobalt phosphide), lawrencite (iron-nickel chloride). Their presence is very significant, since they could not have been produced had solidification taken place in the presence of free oxygen. It is the last-named mineral that is largely responsible for the sweating and rusting which occur in certain irons. The metallic portion of a meteorite consists largely of an iron-nickel alloy, and is arranged in a definite manner, as is shown by the markings developed on etching a polished section. Dr. Farrington himself has established that the nature of the arrangement depends on the ratio of the iron to the nickel in the alloy; irons with about 6 per cent. of nickel have one type, which is characterised by the fine Neumann lines, those with from 7 to 15 per cent. have a second type, showing the broad Widmanstätten bands, and those still richer in nickel have a granular structure. Meteoritic stones are not unlike terrestrial rocks as regards their mineral constitution, but differ from them in their peculiar chondritic or granular structure.

One of the problems in the subject that call for solution is a satisfactory classification of meteorites. That at present in use, which is described in detail by Dr. Farrington, was devised by Gustav Rose, and amplified or modified by Tschermak and Brezina. It is cumbersome, consisting as it does of no fewer than seventy-six groups, and has no real scientific basis. The author refers the reader to a scheme on the lines of the American quantitative classification of rocks which he has himself put forward. This classification has, however, been by no means generally accepted in the case of rocks by petrologists. A promising scheme, which emphasises the relationship subsisting between meteorites, however apparently different their characters may be, was recently communicated to the Mineralogical Society by Dr. Prior. It consists of six groups, of which five may be considered as derived from the first

Digitized by Google

by chemical interaction between certain of the constituent minerals.

At the close the author appends a useful table for discriminating the metallic minerals occurring in meteorites, and has added two indices, one general, and the other giving the falls mentioned in the book.

## ESCAPE OF ELECTRONS FROM HOT BODIES.

*The Emission of Electricity from Hot Bodies.* By Prof. O. H. Richardson. Pp. vii + 304. (London: Longmans, Green and Co., 1916.) Price 9s. net.

THIS work, which is one of the series of monographs in physics published under the editorship of Sir J. J. Thomson and Prof. Horton, deals with the emission of positive and negative electricity from hot bodies. The closely related subject of the conductivity of flames is not included. It will be remembered that a volume dealing with this part of the subject was published a few years ago by Prof. H. A. Wilson.

While it had long been known that hot bodies discharge both positive and negative electricity, the detailed investigation of this important subject was an immediate consequence of the development of the ionisation theory of gases. The author was one of the first workers in this new field of work begun at Cambridge, and with the help of numerous students he vigorously continued his investigations at Princeton University, and more recently at King's College, London. A large part of our knowledge of this subject is due to his investigations.

As a consequence, we have a first-hand account of this interesting subject, written by one who has a full appreciation of the experimental difficulties and the adequacy of the theories proposed. A large part of the volume is devoted to the study of the emission of negative electrons from heated filaments at low gas-pressures, its variation with temperature, the effect of residual gases, and the treatment of the metal surfaces. Although the electronic current is usually large and easily measured, there are in many cases wide discrepancies in the magnitude of the current obtained under similar conditions by different observers. This lack of definiteness in the data seems to result mainly from the part played in the electronic emission by the condition of the surface, and the presence of gaseous or other impurities. A general theory is advanced on the supposition that a metal contains free electrons which obey the gas laws. At high temperature some of the electrons acquire sufficient energy to escape from the metal surface. The theory of the escape of electrons from a hot metal is thus analogous to that of the evaporation of a liquid. This theory seems to explain satisfactorily the rapid variation of the electronic current with the temperature. The author has shown experimentally that energy is expended in the escape of electrons from the metal surface, and that heat is given up to the metal surface when electrons pass into it. The connection of these effects with the contact difference of potential has been carefully examined.

As is well known, there has been considerable difference of opinion in the past as to the origin of the large electronic emission from incandescent bodies. Its susceptibility to conditions, and especially to the presence of impurities, has led some to suppose that part, if not all, of the electronic emission is the result of chemical action between the heated metal and the gaseous or other impurities. The author evidently considers that there is a true electronic emission depending only on the metal, and his contention is certainly strongly supported by the observed fact that a tungsten filament in the highest possible vacuum continues its emission of electrons unchanged with time. On the other hand, the electron current from most metals is very markedly influenced by the previous history of the wire, and is extraordinarily susceptible to the presence of a minute amount of impurity. For example, Langmuir in a recent paper directs attention to the striking fact that the heating of a filament containing thorium in the neighbourhood of the tungsten wire increases the thermionic current of the latter by a million times. While great progress has been made in the last decade in extending our knowledge of this subject, there is no doubt that much work still remains to be done to clear up many outstanding difficulties.

In the last chapter the author discusses the experimental evidence of the emission of positive electricity from heated metals and salts, and describes the ingenious method developed by him to determine the mass of the carriers. The surprising fact is brought out that in the great majority of cases the carriers of positive electricity are atoms of potassium. The reason why potassium, which, even when present only in minute quantities, is an impurity, should be the active element in this emission is difficult of explanation.

In the preface the author mentions that he has not thought it desirable to include an account of the practical applications of thermionic emission, but mentions some of the more important papers in which this side has been discussed. It is to be hoped, however, that when a second edition is called for, the author will devote a chapter to the very interesting application of the thermionic emission to the rectification of alternating currents, and to the magnification of small currents in radio-telephony and radio-telegraphy. It is of great value that students should appreciate the striking way in which the pure science researches in this subject have proved of great technical value.

This book can be strongly recommended to all those who are interested in modern physics as a clear and up-to-date account of our knowledge of an important department of modern scientific research.

## PHYSICS.

(1) *A Student's Heat.* By I. B. Hart. Pp. vii + 376. (London and Toronto: J. M. Dent and Sons, Ltd., 1916.) Price 4*s.* 6*d.*

(2) *Elementos de Física Descritiva para a 4ª e 5ª Classes dos Liceus.* Por Dr. F. J. Sousa Gomes e Alvaro R. Machado. 5ª edição, revista por Alvaro R. Machado. Pp. 528. (Braga: Livraria Escolar de Cruz y Ca., 1915.)

(1) MR. HART'S text-book of heat is intended for use in the higher forms of secondary schools, for advanced students in technical colleges, and for those taking a pass degree examination at the university. The author has included in his book descriptions of many modern methods of determining thermal constants and results of recent experimental investigations. Although the calculus is introduced in the section on thermodynamics, a knowledge of elementary algebra and geometry will suffice for the perusal of the greater part of the book. The text is furnished with a large number of clearly drawn diagrams, but the exposition in some parts is open to considerable criticism.

In the paragraphs dealing with electrical methods of measuring temperature the author assumes his reader to have no knowledge of electricity, and explains the chief points of the simple electric circuit with the aid of a diagram showing cell, ammeter, resistance, and voltmeter all connected in series. In connection with the platinum resistance thermometer, the compensating leads are not made of copper, nor is it usual to standardise the instrument in the way described by the author. The variation of resistance with temperature is represented by $R_t = R_0 (1 + \alpha t + \beta t^2)$. According to the author, $\beta$ is neglected for approximate measurements, and $\alpha = 0{\cdot}00366$; while for more accurate work the constants $\alpha$ and $\beta$ are determined by measuring the resistance at 0° C., 100° C., and $-273°$ C. At the last-mentioned temperature the resistance of a pure metal is known to be zero. Again, when describing the thermocouple method of measuring temperature, on p. 23, we have "the difference in temperature at the junctions *induces* an electromotive force, and the galvanometer registers a *kick*." The formula derived for the expansion of a liquid by the weight thermometer method, on p. 49, is wrong. On p. 86, dealing with molecular velocity and temperature of a perfect gas, it should be made clear that it is the square root of the mean square velocity of the molecules which is proportional to the absolute temperature and not their mean velocity. It is difficult to see how Charles's law for unsaturated vapours is verified by the experiment described on p. 131, since the vapour will be subjected to varying pressures. On p. 182 we have the statement that Newton's law of cooling is an approximation to Stefan's law. This is wholly erroneous, since the law of Stefan refers to loss of heat by radiation alone. Each chapter is furnished with a large number of questions selected from the papers of various examining bodies.

(2) As its title implies, this text-book is purely descriptive in character. The subjects dealt with are mechanics of solids and fluids, light, heat, sound, electricity and magnetism. The ground covered is only elementary, and upwards of 200 pages are devoted to introductory mechanics and properties of matter. No mathematical proofs of the formulæ employed are given, the idea being that the statements are to be regarded as laws to be verified experimentally. While there is nothing novel in the treatment of the subject, the text is accurate, concise, and amply illustrated.

## BIRDS AND THE POET.

*The Birds of Shakespeare.* By Sir Archibald Geikie. Pp. x + 121. (Glasgow: James Maclehose and Sons, 1916.) Price 3*s.* 6*d.* net.

THIS volume—one of the company of books which owe their existence to the tercentenary of Shakespeare—consists of an address delivered by the distinguished author to a country natural history society, and as such it must have served its purpose admirably. Beyond this it makes no pretensions, but it is all that it claims to be, and will fill a vacant place on the shelves of those who do not possess Mr. J. E. Harting's standard work.

In his opening pages the author lays stress on the development of man's feeling towards Nature from Chaucer to Shakespeare, from the simple, unreflective delight in the sights and sounds of the open air to the dawning of a sense of "the mystery of things" and its influence on the human mind; and again, at the close of the lecture, he passes to the further development of reflectivity manifest in the poems of Wordsworth, Keats, and Shelley, where the birds are not merely talked *about*, however poetically, but actually talked *to*, as being, like ourselves, "travellers between life and death." The main body of the volume is taken up with the passages in the plays and poems relating to the several birds, linked together by pertinent observations. Some half-dozen pages are deservedly devoted to that "pleasure for high-mounting spirits"—the sport of hawking, to which the birds of prey owed such consideration as they enjoyed; for, apart from this, Shakespeare shares the depreciatory attitude towards them current in his day and long after, including even the "mousing owl"; but then, as Waterton long ago remarked, from the time of Ovid downwards this useful bird has always been in ill odour with the poets. Passing on to the game birds, we get a too brief account of the various methods of taking them, and the sportsman to whom the "Diary of Master William Silence" is still an undiscovered treasure might have welcomed a footnote sending him to that invaluable work.

Here are one or two points which might receive attention when the book is reprinted. "The Passionate Pilgrim" and "The Phœnix and the Turtle" are drawn upon without any hint that these *réchauffés* are by no means wholly the work of Shakespeare. Loon, "a diver," and loon, "a

Digitized by Google

rogue," are words of distinct origin. With the very doubtful exception of the passage in "King Lear," Shakespeare's "chough" (as the present writer maintained many years ago in the *Zoologist*) is not the Cornish chough (*Pyrrhocorax graculus*), but the jackdaw (*Corvus monedula*), and, to be strictly accurate, Tereus was not the brother, but the brother-in-law, of Philomela.

The numerous illustrations require no recommendation. They are our old familiar friends from Yarrell and Howard Saunders.

## OUR BOOKSHELF.

*The Panjab, North-West Frontier Province, and Kashmir.* By Sir James Douie. Pp. xiv + 373. (Cambridge: At the University Press, 1916.) Price 6*s.* net.

THE editor of the Cambridge series of Provincial Geographies of India made a happy selection when he entrusted the Panjab to Sir James Douie, who during thirty-five years' work as a member of the Indian Civil Service has held the posts of Chief Secretary, Financial Commissioner, and Officiating Lieutenant-Governor; what he does not know of the Province in which he served is not worth knowing. In a series of chapters packed with information he discusses the physiography, ethnology, sociology, history, archæology, and administration of an area of one quarter of a million square miles, comparable in extent, as well as in other respects, with Austria-Hungary. To summarise this amount of information within a limited space naturally prevents the elaboration of detail. The book, in fact, is an epitome of the information contained in the Imperial and Provincial Gazetteers, and in numberless other official publications.

An excellent feature of the work is the large series of photographs, maps, and diagrams. In the illustrations it is pleasant to notice that the personal element is well represented in John Lawrence, Charles Aitchison, Denzil Ibbetson, and Michael O'Dwyer—some of the able administrators for which the Province has been noted—and in those of native celebrities. In a new edition we may suggest the inclusion of some great soldiers—Pollock, Nott, Gough, Nicholson, Edwardes, Roberts, and Donald Stewart. It would also be a help to students to provide a short list of the more useful books dealing with various aspects of history, social life, travel and sport. The mistake (p. 24) of fixing Lord Roberts's march to Kabul in 1898 should be corrected. Every young officer, military and civil, posted to India should possess a copy of this useful book, and it might with advantage be introduced into the geography course in British and Indian schools.

*The Student's Handbook to the University and Colleges of Cambridge.* Fifteenth edition, revised to June 30, 1916. Pp. 16 + 704. (Cambridge: At the University Press, 1916.) Price 3*s.* net.

THOUGH the statements contained in this handbook are not official, the information provided has been compiled from authentic sources and may be regarded as accurate. Parents sending sons to Cambridge will find the guide invaluable, especially the sections dealing with expenses and scholarships.

In view of the recent comparative inactivity of the University there are no additions to this issue of the handbook. Some temporary emergency regulations, occasioned by the war, affecting undergraduates are summarised conveniently, and altogether the general usefulness of the volume has been well maintained.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### Scarcity of Wasps.

THE scarcity of wasps in Cheshire during the passing autumn, noted in NATURE of October 12 by Mr. H. V. Davis, has been equally remarkable in this district (Wigtownshire). Observation extending over very many seasons has convinced me that the abundance of queen wasps in spring is no indication of the number of swarms in late summer and autumn. That appears to be regulated by the character of the weather in June and July, which this year was unusually cold and wet. In the autumn of 1915 there was an extraordinary number of the nests of social wasps, both of the species that build underground and those that found arboreal colonies. In consequence I do not remember ever to have seen so many queen wasps about as there were in May of this year. Presumably each of these started building cells and laying eggs, but even if these hatched out, the cold was fatal to the larvæ (for wasps are essentially lovers of sunshine); no workers were reared to assist in forming the colony, which consequently came to naught. Last year I would have undertaken to find fifty wasps' nests within a radius of half a mile of this house; this year I did not know of one.

HERBERT MAXWELL.

Monreith.

THE past summer has been so remarkable as regards these insects that a few notes from an old observer may be acceptable. The principal fact to be noticed is the extraordinary disproportion between the immense number of queens in spring (I cannot remember so many in upwards of fifty years' observations) and the scarcity of workers in the summer. It is scarcely an exaggeration to say that there were more queens to be seen in the spring than workers when these were most numerous, in September. To go back to the beginning, an entry in my diary on October 18, 1915, states that on digging out a nest poisoned with cyanide two days previously, in which all the active workers had been killed, "a lot of quite lively ones, mostly queens," was found.

There can be little doubt that the cause of the scarcity of nests and workers was the cold and *wet* weather of mid-April. This supposition is supported by the fact that of the only four nests found and taken near this house, two were in fresh (and therefore warm) manure-heaps, one in the roof of the gardeners' bothy, and one in a sheltered hedge bottom. I have no recollection of having ever seen a nest in a dunghill before.

The discrepancy between the number of queens in

Digitized by Google

spring and of nests and workers in summer is so common that I am tempted to think that the more conspicuous, and therefore more often caught, queens are infertile, and the rewards for their destruction wasted. Perhaps some member of the Association of Economic Biologists will take the matter up?

ALFRED O. WALKER.

Ulcombe, Kent.

---

IN reference to the letter of Mr. H. V. Davis (NATURE, October 12, p. 109), I may say that in this district ordinary wasps have been decidedly scarce this year. Reports from several other localities are of the same character. Queens, however, were abudant in the spring (May and June), but I think that only a few survived the wet and cloudy weather.

I make a point of cultivating these insects, as they are extremely interesting to watch, and destroy myriads of flies every summer. There were six embryo nests in my garden in May last, but only one (*Vespa vulgaris*) managed to withstand the vicissitudes of the inclement weather. This nest was a weak one, for when I dug it out on September 20 it consisted of four layers of cells, the top one alone being for small working wasps (1000 cells), while the others were exclusively for queens and drones (1450 cells). This proportion is quite exceptional according to my own observation, for I have commonly found the smaller cells greatly in excess of the others. In a much stronger nest (*Vespa germanica*) which I took here on October 6, 1915, there were 12,900 cells, forming ten tiers, and less than a quarter of the former had been devoted to the rearing of queens and drones.

Very few persons will be inclined to attract wasps to reside in their own immediate neighbourhood, but anyone caring to study these insects should make a few little cavities in dry situations early in April. The queens begin selecting eligible positions in that month (average date, April 17). It is certain that wasps are not so aggressive and violent as commonly supposed. They display remarkable industry and activity, for at midsummer they may be observed streaming to and from their homes during a long working day of eighteen hours! In view of the justified agitation against the house-fly in recent years, it is questionable whether the usual spring campaigns against queen wasps should be encouraged. On a bright summer day in 1913 I carefully watched the entrance of a wasps' nest in my garden, and concluded that the insects brought home at least 2000 flies.

W. F. DENNING.

44 Egerton Road, Bristol, October 14.

---

REFERRING to Mr. H. V. Davis's letter in NATURE of October 12 on the scarcity of wasps, I have taken nests for some years over an area a little less than 1000 acres as follows:—1906, 95 nests; 1907, 61; 1908, 31; 1909, 113; 1910, one (*Vespa rufa*, Linn.); 1911, 85; 1912, 56; 1913, 189; 1914, 21; 1915, 56.

1916: I knew of three *Vespa vulgaris*, Linn., nests, and took one as it hindered ploughing, and in the early part of the season I hived three *Vespa sylvestris*, Scop., nests as there were a very large number of *V. sylvestris*

THE Dartford Naturalists' Field Club this season also experienced a scarcity of wasps; local papers reported the same about Gravesend on the east, and Bexley on the west.

Their nests were very plentiful last year, and so queens were exceedingly plentiful in spring—abnormally so. But later a cold spell nipped those about at the time.

Observers here speak confidently of the persistent hunting of flies by these early queen wasps, out too soon for nectar from flowers, and say the early wasps put down the flies for this summer. Flies were far more numerous last year, and, other things being equal, a beekeeper predicts many flies next summer, because of this season's scarcity of wasps. He remembers such an experience at Green St. Green (Dartford).

On May 27 I saw a note about more wasps than usual at Dudley, a district fairly free compared with the south and west. It was during May when so many early queens were observed here.

S. PRIEST

(Hon. sec., Dartford Naturalists' Field Club).

---

REFERRING to Mr. Davis's letter, it would be interesting to know if the same dearth of wasps has been noted in the cider counties.

I have caught only two here this season (in jars of beer and sugar placed outside), while last year I trapped hundreds.

C. CARUS-WILSON.

Strawberry Hill, Middlesex, October 13.

---

### Glacial Nomenclature and Scott's Antarctic Expedition.

IN the review of my book, "With Scott—The Silver Lining," in NATURE of June 1, the reviewer, among many kindly remarks, takes exception to my use of the word "riegel." He prefers the English word "bar." I have briefly explained my point of view in the *Geographical Journal* (p. 571, December, 1914), but may be allowed to elaborate it a little.

Webster gives fourteen paragraphs dealing with different meanings of the word "bar." One at least of these—the bar of a river—is a geographic term. Why should the reviewer use the Scotch word "corrie" or the French "cirque" (as I use the Welsh "cwm") if not because—as in my case—there is no English word which is not ambiguous? I believe that there was a movement in Oxford to standardise geographic nomenclature. I sent in a memorandum in 1913, but have heard nothing of it lately.

May I refer briefly to further Antarctic questions raised in the review? The "catenary curves" illustrated in my book are not "ordinary denudation curves" in my opinion. They are common in the Alps (*e.g.* above Hospenthal, on the St. Gothard Road), but not in regions of normal erosion. An ordinary water-cut valley only a few hundred yards across would certainly not exhibit the smooth catenary curve of the small empty Antarctic valleys.

The small scale of the photograph of the Discovery

Digitized by Google

through the Royal Society Range is to a large degree answered by what I call the "palimpsest theory" (v., p. 175). In effect the outlet glaciers flow down notches cut by earlier headward (or cwm) erosion. I hope to publish shortly a mass of evidence and illustration in support of this sequence in glacial erosion.

GRIFFITH TAYLOR.

Meteorological Bureau, Melbourne, July 26.

---

Muret Sanders's "Encyclopädisches Wörterbuch" gives "riegel," in addition to the various ordinary meanings of the word "bar," including a bar of soap, eleven other meanings. What advantage is there in the use of a German term over an English term when both have equally varied meanings? The term "riegel" is especially overloaded, as in geography, according to Grimm's "Deutsches Wörterbuch," it is used in South Germany for a "kleine Anhöhe, steiler Absatz eines Berges," and he also quotes its use for a watershed.

Ordinary water erosion would certainly produce a slope with catenary curves if it is operating on suitable rock and under suitable conditions.

The conclusion that the *Discovery* Hut was not erected as designed was not based only on Dr. Taylor's photograph, and there could have been no difficulty in managing the supports on any surface of ice which had not so steep a slope as to be otherwise unsuitable.

The more detailed information regarding the origin of the glacier valleys which Dr. Taylor obviously collected may, as was remarked in the review, explain their origin. Dr. Taylor's further publication will be awaited with interest. THE REVIEWER.

## *ANNEALING GLASS.*

EVERYONE who makes chemical apparatus by blowing glass practises annealing in a rude way by allowing the glass to cool slowly by gradual removal from the flame, or by the use of a smoky flame. In glass works more systematic annealing is effected by slow passage through a long chamber wherein the temperature falls from the incoming to the outgoing end. In the manufacture of optical glass of many different qualities the question of annealing is one of the first importance, as they differ so much in fusibility. Messrs. Hilger have after a careful investigation found the means of arriving at the maximum temperature necessary, and also the necessary rate of cooling, which may progressively become more rapid. Optical glasses may differ as much as 200° C. in the maximum necessary temperature, which temperature may be a long way below any visible softening point. It is desirable not to exceed the necessary temperature, as the very slow cooling at the higher temperature leads to great loss of time.

The method adopted by Messrs. Hilger for testing different specimens of glass is interesting as an example of a physical investigation made with a view to practically useful results. The principle of the method can be described very shortly. Fig. 1 shows a bar of glass supported as a cantilever, and carrying a load. Its edges are ground and polished in the form of two parallel planes. This is set up in an electrically heated muffle, with means for observing the temperature electrically. Polarised light broken up into interference bands by passage through a Babinet's compensator is passed through the glass, and when this is loaded the bands become inclined as shown in the figure, illustrating how perfectly the stress, whether of compression or extension, is proportional to the distance from the neutral axis. If the load is allowed to rest on a support in consequence of the slight yielding of the glass, the rate at which the bands change from the inclined to the straight position can be observed for any known tempera-

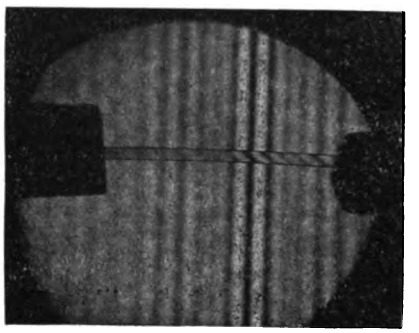

FIG. 1.

ture. Fig. 2 shows two specimens undergoing a change of temperature which sets up strains from the difference in temperature between the interior and the exterior. That the two specimens are very different is only too apparent.

By watching the bands in specimens of glass Messrs. Hilger are able to ascertain when the glass is hot enough to allow the internal strains to be relieved in a convenient time, and whether as the glass cools internal strains are avoided by

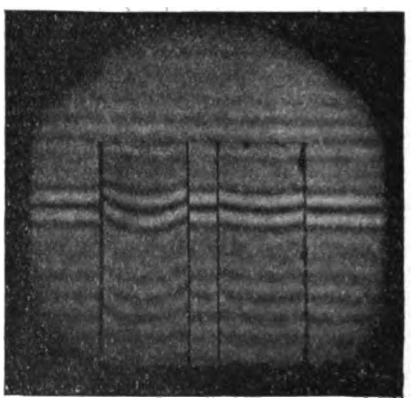

FIG. 2.

sufficiently slow cooling. After a point is reached at which the glass has lost all viscosity the cooling may be accelerated, and though the bands then become curved they straighten out again when ultimately the temperature is equalised. There is no hard-and-fast point at which the glass ceases to be viscous, and so there is a progressive permissible increase in the rate of cooling. Messrs. Hilger have thus shown how annealing may be effected perfectly in the minimum of time. Though

Digitized by Google

the research was carried out with the object of finding how best to anneal blocks of optical glass, the apparatus is available for testing any glass, chemical or otherwise, and Messrs. Hilger, having the apparatus set up in their laboratory, are prepared to test specimens of glass for the trade, and thus provide the valuable information which they are able so easily to obtain.

C. V. Boys.

## *UNIVERSITY AND HIGHER TECHNICAL INSTRUCTION IN FRANCE.*

ONE of the principal articles in the *Revue générale des Sciences* for June 30 is that by Prof. Paul Janet, of the Sorbonne, director of the Higher School of Electricity, concerning the *rôle* of the universities in higher technical instruction, especially in relation to the Bill before the French Senate, at the instance of M. le Goy, to sanction the establishment of faculties of applied science in the universities. The proposed measure is exciting considerable interest, not only amongst the learned bodies in France, but also amongst those engaged in scientific industries. The question has assumed a deeper interest in view of the problems raised by the war and of the position and means of development at its close of the national industries, especially those closely dependent upon chemical and electrical science.

Incidentally the question raised by M. le Goy in his project embraces other deep considerations relating to economic problems, including the right direction and utilisation of capital, the question of tariffs and raw materials, a closer union of capital and labour, and especially the creation of a better educated industrial *personnel* in the scientific control and administration of industry, together with measures for the amelioration of industrial conditions. It is urged with considerable force that there is need of a much closer understanding between men devoted to pure science and those engaged in the higher technical industries. The former are often ignorant of the difficulties which beset the engineer and manufacturer, despite the systematic methods he employs in the actual production of commodities; whilst the latter, resenting the accusation that they lack all scientific spirit, do not hesitate to apply derisively the epithet "Sorbonnique" to the science which is incontinently thrust upon them.

Only when this antagonism is entirely removed by a closer sympathy, understanding, and appreciation, on the one hand, of the potentialities of pure science, and on the other of the difficulties which beset its translation into terms of production, can there come that union of effort upon which the successful development of industry depends. In the case of the electrical industry it is freely admitted by all concerned that it finds its solid base in

The article goes on to consider the existing resources for the training of the expert engineer, and passes in rapid review the faculties of science existing in the universities of France and their competence to train the future technologist; the technical institutes, such as the Chemical Institute at Nancy, founded in 1890, and the Electro-Technical Institute at Grenoble, founded in 1892; the Ecole Polytechnique and the Central School of Arts and Manufactures at Paris, and other special schools in France. An unfavourable view is taken, however, as to the competence of the faculties of science, which have never shown any appreciation of the needs of industry, adequately to train the men, who in fact do not really seek them, destined for industrial pursuits. A firm distinction is drawn between the ideals and aims of the university and the functions of the schools of practical science. The former need for their realisation absolute freedom and long leisure, since their purpose is the exploration and discovery of natural laws, the attainment of exact knowledge as the grand end of their existence, and the moral rather than the material progress of humanity. Research is with them the end, and teaching only the means. The latter, to achieve their purpose, require direct contact with industrial problems, and the due and serious employment of the time of their students, with strict discipline and method and supervised work.

In order to bring the universities into closer touch with industry, it is suggested that they should, with the collaboration of practical men, establish scientific institutes preparatory to industry. It is further proposed to found a very few higher technical schools for more advanced industrial training and research, established and controlled directly by men eminent in industry, yet aided by the State and directly linked with the Ministry of Public Instruction.

## *PUBLIC SCHOOLS AND OTHERS.*

"PUNCH" of September 27, under the title of "Public Schools," prints a poem of which the last two verses are as follows:—

*Spite of the anti-classicists' arraigning,*
*Spite of the ink so petulantly spilt,*
*Not by exact laboratory training,*
*Not by the test-tube character is built.*

*Only in fields of emulous endeavour,*
*Fired by the teaching of the famous dead,*
*Public-school boys, who play the game for ever,*
*Grow into leaders and inspire the led.*

PUBLIC SCHOOLS: AN ANSWER.

Dear *Punch*, your poet praises public schools,

Digitized by Google

Again, those test-tubes, which his words abhor,
And cheap thermometers with paper zeroes,
All made in Germany before the war,
Were not unknown to many of their heroes.
[Just now sweet girls in improvised pavilions
Are turning English test-tubes out by millions.]

Boys from our "public schools" (including those
Provided, non-provided, and the rest of it),
When once the opportunity arose,
Quitted themselves like men, and made the best of it.
The highest praise for such a band of brothers,
Would be: "Each did his duty like the others."

Then, as to leadership, I knew a lad,
By nature quite unqualified to grapple
With Greek and Latin verses. This was bad.
Worse still, a Jew, he never went to chapel.
And yet he learnt, in spite of missing sermons,
His duty to his men, and to the Germans.

Perhaps the Duke was right in his remark,
That old, apocryphal, and hackneyed saying;
And Eton Playing-fields, and Regent's Park,
And all fair fields where British boys are playing,
Have proved of higher value to the nation
Than classical, or modern, education.

W. D. E.

## NOTES.

THERE have been much overlapping and unevenness of distribution in connection with the food parcels sent to British prisoners of war; and little scientific guidance has been sought or given as to the food-values of the things included in the parcels. The first of these defects will be remedied by a scheme which is to be brought into effect on December 1. It is announced that the Central Prisoners of War Committee, recently established by the British Red Cross Society and the Order of St. John, has, with the authority of the Government, now made the necessary arrangements for co-ordinating and controlling the work of the various associations and individuals at present sending parcels to British prisoners of war in Germany and other enemy and neutral countries. These arrangements have been made with the view of securing:—(1) That every prisoner shall receive an adequate supply of the comforts in the form of food, etc.; (2) that the excellent work being done at present by associations and individuals shall be disturbed as little as possible; (3) that overlapping and consequent waste shall be reduced to a minimum. In order to attain these objects the following arrangements have been made:—(1) All parcels must be sent through the Central Committee, London, S.W. We suggest to the committee that guidance is needed as to the most suitable things to send from the point of view of food-values. A prisoner of war doing moderate work requires a daily ration which has an energy value of 2500 calories, and may be made up of proteins, 100 grams; carbohydrates, 400 grams; and fats, 50 grams. It is possible to combine all these constituents in a single foodstuff, or to see that the ratios are roughly supplied by the combination of several things in a parcel. The British Science Guild has appointed a committee to make suggestions relating to food parcels, and the Central Prisoners of War Committee should enlist its aid or that of other food experts in order to advise associations as to the most suitable constituents of the parcels.

THE Board of Agriculture announces that an estate of 2363 acres near Patrington, in the East Riding of Yorkshire, about fifteen miles distant from Hull, has been acquired under the provisions of the Small Holding Colonies Act, 1916, for the purpose of a land-settlement colony of ex-service men. The soil is a rich alluvium capable of producing very heavy crops. This colony, when fully developed, will consist of a central farm of about 200 acres and sixty small holdings of "mixed farming" type, averaging about 35 acres in extent. The equipment of each of the latter will include a comfortable cottage and the necessary farm buildings for carrying on the holding. The central farm will be under the management of a director, and will be equipped with machinery, implements, horses, etc., which will be let out on hire to settlers requiring them. Selected applicants will, if necessary, receive preliminary training by working on the central farm under the supervision of the director, and be paid wages until such time as they are considered capable of working a holding independently. They will then be allotted, at a reasonable rental, land near their cottages which, if of less extent than the average-sized holding above indicated, may be afterwards increased by taking land from the central farm. Co-operative methods will be adopted for the purchase of requirements and the consignment and disposal of produce. This is, we believe, the first experiment of its kind in this country, and its development will be watched with great interest. For some years there has been a great controversy as to the merits of schemes of this kind, and now arises the opportunity for the large-scale test. The experience gained is likely to be of great value, deciding whether or not such colonies can be run on an economic basis.

PROF. A. S. DONNER, director of the observatory at Helsingfors, has presented to the University, of which he was formerly rector, the sum of 8000*l.*, to ensure the continuance, and indeed the completion, of the "Catalogue photographique du Ciel, Zone de Helsingfors," begun under his direction in 1890. Hitherto the work has been paid for, partly by the University, partly by Prof. Donner out of his private means. The sum now allotted by him is intended to cover all expenses for twelve years, when, at its present rate of

Digitized by Google

will take as his subject "Some Aspects of Lord Kelvin's Life and Work."

THE address of the retiring president, Sir Joseph Larmor, at the anniversary meeting of the London Mathematical Society, to be held on Thursday, November 2, at 5.30, at Burlington House, will deal mainly with "The Fourier Harmonic Analysis: its Practical Scope and its Limitations."

THE Cardiff Naturalists' Society, the most influential body of its kind in Wales, attains its jubilee next year. It is hoped to signalise the event in a useful way by producing a complete fauna of Glamorgan.

A SINGULAR phenomenon excited extraordinary attention at and round Cardiff on the evening of October 16. About 6.25 a narrow bar of light appeared in the north-north-west, about 6° long and 1° broad, some 40° above the horizon, the sky being mostly overcast at the time. By 6.35 it had shifted to the north, and ten minutes later to its former situation, whilst a similar appearance was seen in the north-east, a good deal fainter than the other. The beam just mentioned was of an angry ruddy colour, and fitfully illuminated the surrounding haze. Along the northern horizon all this time there was a glow, probably of auroral origin, and the Rev. John Griffith informs the writer that the shaft of light was, in his opinion, possibly auroral also, he having witnessed a similar phenomenon some years ago.

WE notice with regret the announcement of the death on September 14, in his sixty-first year, of Prof. Josiah Royce, distinguished for his contributions to philosophy, logic, ethics, and psychology, and professor of the history of philosophy at Harvard University from 1892 until his recent retirement.

THE death is announced, in his fifty-third year, of Dr. J. H. Kastle, research professor of chemistry since 1911 at the agricultural experiment station in connection with the State University of Kentucky. He had previously been chief of the division of chemistry in the hygienic laboratory of the U.S. Health and Marine Service from 1905 to 1909, and professor of chemistry at the University of Virginia from 1909 to 1911. He was the author of treatises on the chemistry of metals and the chemistry of milk, as well as of articles in the *American Chemical Journal*.

AT a hearing before a New York official budget committee it was recently stated that the attendance at the American Museum of Natural History for the year ending June 30, 1916, was 870,000, as against 664,215 for the previous year. The increase was attributed to the larger number of visits to the museum by classes from the schools. During the same period the attendances at the Metropolitan Museum of Art, the New York Zoological Garden, and the Aquarium have considerably decreased.

THE death is announced of Dr. David Maron, a research chemist, whose work is referred to as follows in the *Times* of October 20:—"Dr. Maron was a Russian, aged fifty-two, who had been resident in England for many years. He claimed to have invented a new process by which the output of high-explosive shells could be accelerated, and he carried on his operations at a factory near London. On September 14 there was a serious explosion at the works. The Press Bureau announced that 'an explosion has occurred to-day at a factory where the manufacture of explosives on a small scale for the Government had recently been commenced. The casualties are not numerous, present reports recording five killed and fifteen injured.' Dr. Maron was seriously injured, and he died on September 17."

IN addition to the awards announced in April for papers read at the meetings, the council of the Institution of Civil Engineers has made the following awards for papers published in the Proceedings without discussion during the session 1915–16:—Telford premiums to Messrs. Hubert Mawson (Liverpool), T. W. Keele (Sydney), R. W. Holmes (Wellington, N.Z.), W. Fairley (London), J. M. Greathead (Johannesburg), T. C. Hood (Manmad, India), and J. B. Ball (London); the Manby premium to Mr. W. C. Cushing (Pittsburg, U.S.A.); and the Crampton prize to Major C. E. P. Sankey (London). The Indian premium for 1916 has been awarded to Sir John Benton (Eastbourne).

THE President of the Board of Trade has appointed a committee to consider the position after the war, especially in relation to international competition, of the lead, copper, tin, and such other of the non-ferrous metal trades as may be referred to the committee, and to report what measures, if any, are necessary or desirable in order to safeguard that position. The members of the committee are:—Sir Gerard Albert Muntz, Bt. (chairman), Mr. C. L. Budd, Mr. C. Cookson, Mr. C. W. Fielding, Lieut.-Col. A. J. Foster, Mr. A. W. Tait, and Mr. A. H. Wiggin. The secretary is Mr. J. F. Ronca, to whom all communications relating to the committee should be addressed at 7 Whitehall Gardens, S.W.

AT the statutory meeting of the Royal Society of Edinburgh, held on October 23, the following office-bearers and council were elected:—*President*, Dr. J. Horne; *Vice-Presidents*, Dr. B. N. Peach, Sir E. A. Schäfer, the Right Hon. Sir J. H. A. Macdonald, Prof. R. A. Sampson, Prof. D'Arcy Thompson, Prof. J. Walker; *General Secretary*, Dr. C. G. Knott; *Secretaries to Ordinary Meetings*, Prof. A. Robinson, Prof. E. T. Whittaker; *Treasurer*, Mr. J. Currie; *Curator of Library and Museum*, Dr. A. Crichton Mitchell; *Councillors*, Dr. W. B. Blaikie, Principal O. C. Bradley, Dr. R. S. MacDougall, Dr. W. A. Tait, Dr. J. H. Ashworth, Prof. C. G. Barkla, Prof. C. R. Marshall, Dr. J. S. Black, Sir G. A. Berry, Dr. J. S. Flett, Prof. M. Maclean, and Prof. D. Waterston.

TYPHOID inoculation was the subject of a question by Mr. Chancellor, the member for Haggerston, in the House of Commons on October 18. Mr. Forster, replying, said that up to August 25, 1916, of the total cases finally diagnosed as typhoid fever amongst the British troops in France, 903 were amongst inoculated men and 508 amongst uninoculated men. There were 166 deaths, 47 of which were amongst the inoculated and 119 amongst uninoculated. To the same date there were 2118 cases of paratyphoid fever, 1968 amongst inoculated men, and 150 amongst men who had not been inoculated. There were 29 deaths, 22 of which were amongst the inoculated and 7 amongst the uninoculated. From these figures it will be seen that the case-mortality per cent. for typhoid fever is, among the inoculated 5·0, and among the uninoculated 23·4; for paratyphoid, among the inoculated 1·12, and among the uninoculated 4·66—a striking testimony in favour of inoculation.

THE exhibition of kinematograph films of Capt. R. F. Scott's Antarctic expedition has been revived after an interval of nearly two years, and is being shown twice daily at the Philharmonic Hall by Mr. H. G. Ponting. Mr. Ponting, during the year he

Digitized by Google

spent with the expedition, availed himself of every opportunity of making kinematograph records of the life and work in the Antarctic, and has a remarkable series of pictures to show. The pictures of Weddell seals and Adelie penguins are excellent records of Antarctic animal life, but cannot compare in the skill and patience required with the film of penguin chicks breaking out of their eggs or of skua gulls swooping down on a penguin rookery and stealing unguarded eggs. The film showing the bows of the *Terra Nova* breaking into the pack gives a good idea of how a polar ship forces her way among ice. The films of sledging and camping show Capt. Scott and his four companions in the first few days of their southward march. These have an interest that can never fade in any field of heroism. Mr. Ponting was happily inspired in reopening his exhibition at the present time, not only for the high educational value of the pictures themselves, but in recalling the devotion and self-sacrifice that men may show in peaceful endeavour.

WE learn from *Symons's Meteorological Magazine* that Mr. Edward Mawley died on September 15, at seventy-four years of age. The following particulars of his work in meteorology are from an obituary notice in our contemporary:—Mr. Mawley was elected a fellow of the Royal Meteorological Society in 1876, and served continuously on the council from 1881 to 1908. He was president in 1896–98, when he gave two addresses of great value. The first was on "Shade Temperature," giving the results of a lengthy series of experiments with different patterns of thermometer screen, which resulted in the adoption of the Royal Meteorological Society's modification of the Stevenson screen. The second was on "Weather Influence on Farm and Garden Crops," and may be said to have intertwined the two main branches of his life-work. After retiring from the presidency he acted as secretary at the meetings of the society from 1898 to 1901, and throughout the whole time his influence was always exercised in extending the usefulness of the society and increasing its dignity. Mr. Mawley commenced his meteorological observations at Richmond, Surrey, in 1870, and in 1873 he went to Addiscombe, near Croydon, where his meteorological observations were greatly extended. In 1883 he moved to Berkhamsted, where he soon created one of the finest private meteorological stations in the country.

THE meeting of the Gilbert Club, to which we referred in our issue of October 12, was held in the rooms of the Royal Society of Arts on Wednesday of last week. The Right Hon. Lord Moulton occupied the chair. Mr. Conrad Cooke, the hon. secretary, read his report recording the past history and present position of the club, and in it he paid a warm tribute to the memory of Prof. Silvanus Thompson, expressing the irreparable loss to the club, of which he was the life and soul, by his lamented death. Mr. Charles Benham, of Colchester, as representing the hon. treasurer, read the hon. treasurer's report. Both these reports were adopted. The members then devoted themselves to a discussion as to the disposal of the property of the club, including thirty-four copies of the translation of Gilbert's "De Magnete," issued by the Gilbert Club, and letters were read from Lord Rayleigh, Sir Joseph Larmor, Dr. Singer, of Oxford, Mr. W. M. Mordey, Mr. James Paxman, and others, in which various suggestions were made, and a general discussion followed. The general consensus of opinion, however, appeared to be that the proceeds should be devoted to forming the nucleus of a fund to establish a Gilbert scholarship for physical science in the Royal Grammar School at Colchester, in which in all probability William Gilbert was himself a scholar. Lord Moulton, in summing up the discussion, pointed out the legal aspect of the question, giving it as his opinion that the meeting was not competent to dispose of the property of the club outside its original constitution without giving notice to the members beforehand of the suggestion to be proposed. He considered it advisable that the meeting should be adjourned for three months in order that this should be done. Lord Moulton's recommendation was unanimously adopted.

IN the October issue of *Man* Mr. St. George Gray describes a remarkable chipped flint implement found in British Honduras. It is 19¾ in. in length, chipped throughout, with a straight, chopper-like edge on one side, and on the other two tapering projections. In general character it resembles other large and occasionally serrated implements found in Honduras and now in European museums. No suggestion is made about the possible use of such an implement; but the theory may be hazarded that it bears some ritualistic significance, and that it may have been used in sacrifice or for some similar religious purpose.

DR. A. C. HADDON contributes to the October issue of *Man* a useful article on "Kava Drinking in New Guinea," based partly on published materials and partly on information collected for the first time from friends who have visited the island. The question is important, because Kava drinking has been regarded as a criterion of a certain definite migration, or series of migrations, into Oceania. The root of the pepper plant (*Piper methysticum*) is chewed, not only by grown-up men, who take part in the feast, but also by boys, to whom the drink is still forbidden, and who, together with the women, are not allowed access to the feasting assembly. It is then filtered through grass in a coconut shell, and a traveller who drank it found that it possessed powerful intoxicating properties. It was apparently used to produce mental excitement during some form of tribal ritual. In British New Guinea the custom prevails among three cultures: those of the Kabiri, Mawata, and Maringara. Dr. Haddon supposes that it might readily spread from the Kabiri to the bush peoples behind the Fly delta, but we are in the dark as to the date of this possible drift. There seems to be no reason to believe that it was imported into the Fly estuary area on the south coast of Netherlands New Guinea by a migration or cultural drift by sea. His own opinion is that it has come overland, possibly from Astrolabe Bay. This must, however, remain doubtful until we know more of the races in the interior of New Guinea.

THE psychology of the organised group game is the subject of the fourth Monograph Supplement to the *British Journal of Psychology*. The author, M. J. Reaney, in her introduction, considers the problem of play in general, and summarises the various theories, both physiological and biological, which have been put forward to account for the phenomena of play. She then reviews the types of play leading up to the organised group game, which occupies such a prominent position in the life of modern England. The relation between the type of game played and the degree of racial development is brought out, showing that the organised group game appears only in races which have reached a stage of development in which co-operation is combined with division of labour and loyalty to a leader. She suggests, too, that this form of play gives an outlet to instinctive tendencies for which civilised life affords little scope. In an investigation worked on the principle of correlation she found a direct correspondence between general ability and success at games. The paper will be of particular

Digitized by Google

interest at the present time, when the place of games in education is so much discussed, and when the English habit of "playing the game" is showing its value. Apart from the scientific value, antiquarians and historians will find much that is interesting.

DR. HAMLYN-HARRIS and Mr. Frank Smith contribute some valuable notes to the Memoirs of the Queensland Museum, vol. v., on "Fish Poisoning and Poisons Employed among the Aborigines of Queensland." Considering the widespread practice of fish poisoning, the authors hold that it is not unjustifiable to assume an independent origin among the Australian aborigines, and the evolution of an empirical knowledge of efficient piscicides. Having regard to the very considerable number of plants used for this purpose, the varied properties of the poisons obtained from them, and the skill and knowledge displayed in their preparation, the intelligence and reasoning powers of the preparers would seem to be of a higher standard than that generally attributed to them.

THE Rev. S. Graham Birks contributes a lengthy paper on Megalichthys to the Transactions of the Natural History Society of Northumberland, Durham, and Newcastle-upon-Tyne, vol. iv., part 2. The fossils described belong in part to the Hancock Museum, Newcastle-upon-Tyne, and in part to the Manchester Museum, some of which have not been previously described. The result of this investigation, it is contended, seems to show that the position of Megalichthys in the family Osteolepidæ is by no means secure. There are, indeed, indications that the classification of the Rhipidistia is in an unsatisfactory state. According to the author, although Megalichthys is not itself the ancestral type of the Stegocephalian Amphibia, there can be little doubt that the study of this genus leads inevitably towards the conclusion that its affinities are with the ancestral type, and that the Stegocephalia were evolved from a similar fish, and probably from a nearly related form. A number of very beautiful photographs add much to the value of this work.

MESSRS. HERON-ALLEN AND EARLAND have issued a report (Trans. Linn. Soc., London, Zool., vol. xi., part 13, 1916), illustrated with five excellent plates, on the Foraminifera collected during the cruise of Prof. Herdman's steam-yacht *Runa* off the west of Scotland in 1913. The material examined consisted of shore-sand and dredgings from comparatively shallow waters—sixty fathoms being the greatest depth. A list is given of the twenty-five stations at which the material was obtained, the more noteworthy species from each being indicated, and following this is a systematic account of the 324 species and varieties identified in the gatherings. A new species, *Halophragmium runianum*, and a new variety of *Lagena pulchella* are described; twenty-seven species are recorded for the first time from British waters, and a considerable number make their appearance for the second time only in a British list. The richest material was a lump of mud of about 3½ lb. weight, dredged from twelve fathoms in Loch Sunart, which yielded 203 species and varieties of Foraminifera. The memoir forms an important contribution to our knowledge of the Foraminifera of the British area.

THE report on the survey operations in New Zealand for the year 1915-16 has been received. Despite the difficulties it had to contend with in shortage of surveyors and of funds, the department records that the acreage of the settlement survey is considerably in excess of the previous year, while the cost per acre has been decreased. On the other hand, little triangulation was done, and shortage of paper seems to have delayed the publication of several maps. A feature of the report is the inclusion of a map of Anzac and the Suvla Bay area on a scale of one inch to a mile, with the heights and trenches shown. Some notes on the operations accompany the map. It is fitting that the Survey Department should make this record of the gallant endeavours of the New Zealanders and Australians in Gallipoli.

IN connection with the navigability of Hudson Bay and its value as an outlet for Canadian grain, a useful list of arrivals and departures of ships at and from Moose Factory has been compiled by Mr. J. B. Tyrrell (Papers and Records of the Ontario Historical Society, vol. xiv.). The record shows that from 1751 to 1880 not a single year passed without at least one ship arriving at Moose Factory, generally in August or September, but occasionally in July or October. The ships left again in August or September. Furthermore, Mr. Tyrrell points out that for eighty years previous to 1751, and for thirty-five years after 1880, ships sailed from Britain to Moose Factory bringing supplies, and returned with furs. When it is remembered that these ships were generally old sailing vessels, and that as a rule no attempt was made to send more than the one ship a year, the record is evidence that Hudson Strait and Bay could easily be navigated by steamers for some three months at least every summer.

TWO papers by Dr. L. V. King on the "Linear Hot Wire Anemometer" have been reprinted from the Journal of the Franklin Institute, January, 1916. In these papers the mathematical theory of the instrument and the uses to which it may be put are discussed by the author. The instrument consists essentially of a fine platinum wire carrying an electric current. The temperature of the wire depends on its resistance and the strength of the current, and also on the rate at which it is cooling, since the wire, being very fine, has little capacity for heat, and the energy supplied by the current must just balance the loss by radiation and convection. The loss by convection is naturally dependent on the velocity of the air current in which the wire is placed, and it is claimed that by suitable measurements of the current and the resistance the velocity of the air to which the wire is exposed can be measured with an accuracy of less than 1 per cent. There are obviously many cases where such an instrument can be usefully employed, notably in mapping out the stream lines in two-dimensional motion, where the wire can be placed perpendicularly to the plane of motion. Wires of about 1/400 in. diameter are used, so that very little interference with the flow of air is caused.

MR. MURRAY'S new list of announcements includes the following forthcoming books of science in addition to those to which attention has been directed already in our columns:—"The War and the Nation: a Study in Constructive Politics," by W. C. D. Whetham—the book will deal with such topics as land, coal and railways, science and industry, and with those fundamental racial problems made acute by the great loss of life caused by the present war; "Volcanic Studies in Many Lands," by the late Dr. Tempest Anderson, second series—the volume is intended as a memorial to the author by the Yorkshire Philosophical Society, and will contain the results of further visits to the Lipari Islands, Vesuvius (after the outburst in 1906), and to Etna, together with photographs taken after the great eruptions of the Soufrière and Mont Pelée; "Horses," by R. Pocock, with a preface by Prof. J. Cossar Ewart; and "British Agriculture: The Nation's Opportunity, being the Minority Report of the Departmental Committee on the Employment of

Digitized by Google

Sailors and Soldiers on the Land, together with some Considerations by a Free Trader in Favour of the Polity therein Advocated."

THE following volumes are in preparation for appearance in the "University of Michigan Studies" (*New York: The Macmillan Company*):—Contributions to the History of Science, part ii., "The Prodromus of Nicholas Steno's Latin Dissertation on a Solid Body Enclosed by Natural Process within a Solid," translated into English by Prof. J. G. Winter, with a foreword by Prof. W. H. Hobbs, illustrated; part iii., "Vesuvius in Antiquity," passages of ancient authors, with a translation and elucidations, by F. W. Kelsey, illustrated; Scientific Series, vol. ii., "Studies on Divergent Series and Summability," by Prof. W. B. Ford.

## OUR ASTRONOMICAL COLUMN.

TWO LARGE FIREBALLS.—On October 20 at 8h. 14m. and 10h. 34m. p.m. large fireballs were observed. The first was seen by Mr. J. E. Clark, of Purley, Surrey, and it was estimated as twice as bright as Venus. The path was 82°+62° to 79°+35°, and its duration four to five seconds. The second was seen by Mrs. Fiammetta Wilson at Totteridge, Herts, and by Mr. Denning at Bristol. It appeared as a ball of fire streaming slowly along in a level course about 8° above the northern horizon. This fireball was at a great distance from the observers, and probably over the southern region of Scotland. It probably emanated, like Mr. Clark's fireball, seen earlier on the same night, from a radiant near Zeta Herculis low in the N.W. sky.

ENCKE'S COMET.—Further particulars of Dr. Max Wolf's recent observation of Encke's comet are given in *Astronomische Nachrichten*, No. 4861. The search for the comet was undertaken at the instigation of Dr. Kritzinger, and eight plates were taken at different times during August and September, with exposures amounting altogether to about thirteen hours. The last two exposures were made on September 22, in a very clear sky, and though the plates were on the point of being regarded as failures, the use of lower magnifying power easily revealed the comet, at a point about 20′ from the position given by the ephemeris. The comet appeared on both plates as a faint nebulous patch, with an extremely small condensation, and the displacement of the images in the interval between the exposures corresponded precisely with the ephemeris. The photographs were taken with the 71-cm. reflector, which was guided to follow the probable motion of the comet. The observation is of special interest from the fact that the comet was not far from the aphelion point of its orbit.

INTERNAL MOTION IN SPIRAL NEBULÆ.—An investigation of internal motions in the spiral nebula Messier 101 has been undertaken by A. van Maanen (Proc. Nat. Acad. Sci., vol ii., p. 386). In the first instance measures were made with the stereocomparator on two photographs taken by Ritchey in 1910 and 1915, and strong evidence of motion, even in this short interval, was obtained. Other plates, taken with the Crossley reflector of the Lick Observatory in 1899, 1908, and 1914, were afterwards included in the discussion. The resulting data depend upon measures of eighty-seven nebulous points and thirty-two comparison stars. Relatively to the mean of the comparison stars, the annual motion of translation of the nebula was found to be +0·005″ in R.A. and −0·013″ in declination. The mean rotational motion is 0·022″ left-handed, and the mean radial motion 0·007″ outward. The measures further indicate a small, but scarcely trustworthy, decrease of rotational motion with increasing distance from the centre. At the mean distance of 5′ from the centre, the rotational motion of 0·022″ corresponds to a period of about 85,000 years. If the parallax were known, and if it could be assumed that the movements were in elliptical orbits, the central mass could be calculated. A comparison with the average translation of spiral nebulæ determined by Curtis suggests a parallax of 0·005″, while a comparison of the cross-motions with the known radial velocities of some of the spiral nebulæ leads to 0·0003″. The corresponding central masses are 30,000 and 140,000,000 times that of the sun, and the corresponding orbital motions 21 and 345 km./sec. Evidence of rotation has also been found in Messier 81.

## THE ASSOCIATION OF TECHNICAL INSTITUTIONS.

A LARGELY attended general meeting of the members of the Association of Technical Institutions was held on October 20-21 at the Imperial College of Technology and Science, under the presidency of Sir Alfred Keogh, K.C.B., the president of the association, with the view of discussing educational questions bearing upon the work of technical schools and colleges. The Right Hon. A. H. Dyke-Acland, the chairman of the executive of the governors of the Imperial College, extended a welcome to the members and referred to the splendid service which Sir Alfred Keogh, the rector of the college, in his capacity of director of the Army Medical Service, was rendering to the nation.

The conference was addressed in the first instance by Lord Haldane, Chancellor of the University of Bristol, who took for his subject "Education after the War, with special reference to Technical Instruction." He made clear in his address that unless technical education was based upon large ideas and was penetrated by sound knowledge it must surely fail. He deprecated most strongly the current controversies which sought to place the teaching of the humanities and natural science in unfriendly relation. Knowledge was one and indivisible. The study of fine literature and of the thought it embodies was just as needful to the complete training of the human being as the study of mathematics or of the phenomena of Nature, since the object of all true education was a wider, a more penetrating and stimulating vision. The teaching of the higher mathematics could, if taught in the right way, be made as stimulating as the classics. There was a great awakening in the nation, induced by the events of the war, to the paramount necessity for knowledge. Education and business were not really in two compartments. Rightly considered, the successful pursuit of manufacture and commerce depended for its permanence and value upon sound methods of education and the acquisition of accurate knowledge. Many apt and clear illustrations in support of this contention were adduced from the sphere of chemical, physical, and electrical science and practice. In the domain of applied science attention was directed to the fact that London was the great centre of the world's trade in furs, but that in order to make the furs marketable to the consumer we exported them to foreign countries, notably to Saxony, where alone they could be dyed and treated with suitable effect. The aloofness between the man of business and the man of science must cease, and all classes from the workers upwards, amongst whom there was splendid raw material, must receive the benefits of scientific training. We must have a higher standard of knowledge not only for managers, but for workmen also, if the position of

Digitized by Google

the nation industrially and commercially is to be maintained in face of the fierce competition of the advanced nations of the world. The nation is really entering upon the most critical period of its history. The old spirit was splendid, but it will not avail against modern science any more than we could make progress on the Somme without modern science in furnishing us with the great artillery and high explosives required for battering down the trenches before us. Undue specialisation in secondary schools was undesirable in the best interests of education.

Lord Haldane's address was followed by a valuable paper by Sir A. Trevor Dawson, of Vickers, Ltd., on "Education after the War, with special reference to Engineering Instruction," in which he strongly urged the desirability of apprenticeship beginning at an earlier age than at present, and that the most capable boys should devote a portion of each day to the workshop and the rest to the school, and that every encouragement should be given to capable and talented boys, with a view to their being sent on to the technical college or university to complete their theoretical training, serving their vacations in the works so that they may have the advantage of special courses of advanced work on experimental research. The council of the association was instructed to prepare a public statement dealing with the immediate necessity for the further development of the means of scientific and technical education, and a resolution was passed calling upon Parliament to abolish all forms of exemption from school attendance below the age of fourteen, and to require compulsory facilities for continued education up to seventeen years of age, extending to at least six hours per week within working hours, for all persons employed who have left school. A further resolution was passed to invite the governing bodies of the various agricultural schools and colleges to join the association. On Saturday, October 21, a valuable and suggestive paper was read by Major Robert Mitchell, director of the Regent Street Polytechnic on "What Can Be Done to Train Disabled Sailors and Soldiers in Technical Institutions?" The facilities existing in London for the training of such disabled men in various occupations, and the success which had followed the work, together with the necessity for its further extension throughout the country, were fully set forth.

## RECENT WORK ON TSETSE-FLIES.

THE tsetse-flies (Glossina) continue to occupy the attention of entomologists working in tropical Africa. Dr. W. A. Lamborn has now published (*Bull. Entom. Research*, vii., part 1) a third report of his investigations into the habits of these flies in Nyasaland (see NATURE, vol. xcvii., p. 90). He believes that an abundance of the flies usually indicates the presence of "big game" in the neighbourhood; yet he doubts whether the destruction of game would be effective in reducing the numbers of the fly, because "the game, if severely harassed, will retire [to surrounding areas] during the dry season, when only it is possible to hunt, returning in the wet and probably bringing more flies with it." In the same number of the bulletin there is also a paper by Ll. Lloyd on *Glossina morsitans* in northern Rhodesia. His observations show that in districts where game is scarce tsetses are often more numerous and troublesome than where game is plentiful; he suggests that this is because the flies, in the absence or scarcity of other mammalian prey, must attack man in larger numbers and with a more violent hunger. Mr. Lloyd, like Dr. Lamborn, finds males much more abundant than females in ordinary collections of Glossina, but Dr. Lamborn points out that the proportion of females is largely increased when flies are caught beneath an umbrella or resting on trees, approaching the equality with the males which is seen in flies reared from puparia. Both writers have interesting notes on species of Mutilla (described by R. E. Turner in the same number of the bulletin), the larvæ of which are parasitic in the pupæ of the tsetses, while Dr. Lamborn has shown that a small chalcid (*Syntomosphyrum glossinae*), believed also to be a parasite of the Glossina, is really a hyperparasite on the Mutilla.

A convenient and useful summary of our knowledge of the tsetse-flies ("Notice sur les Glossines ou Tsétsés") by E. Hegh has been published in London under the auspices of the Belgian Colonial Ministry. It serves as an introduction to the structure, life-history, and classification of the insects in tropical Africa generally, but with special reference to the Belgian Congo. M. Hegh begins his historical introduction with the work of Bruce in 1895–6, and seems to ascribe to that distinguished surgeon the discovery that tsetse-flies carry disease. The deadly action of Glossina on European domestic beasts was well known to Livingstone during his early African journeys, and in his "Missionary Travels and Researches" (1857) he described the effect of the tsetse's bite on cattle and horses. With a seeming prevision of modern discoveries, he wrote of the "germ" of a poison "which enters when the proboscis is inserted to draw blood," and which "seems capable, although very minute in quantity, of reproducing itself." Bruce's contribution to the subject was the demonstration of this "germ" as a flagellate blood-parasite or Trypanosoma.

G. H. C.

## ZOOLOGY AT THE BRITISH ASSOCIATION.

THE papers read in Section D were devoted chiefly to the consideration of problems arising out of the war. An account has already appeared in NATURE for October 19 of the papers on fisheries.

### *Flies.*

Mr. F. M. Howlett gave a lecture dealing with the occurrence, habits, life-history, and means of prevention and destruction of the principal insects which have been troublesome during the campaign in France and Flanders. In another communication he surveyed briefly the known facts regarding the senses of insects, and gave an account of his observations, made in India, on the extraordinary attractiveness for the males of certain species of flies of *iso*valeric aldehyde, *iso*eugenol, and methyleugenol.

Miss O. C. Lodge gave an account of studies on the habits of flies in relation to means employed for their destruction. The best bait for blow-flies was found to be liver, brain, and fish which had been already attacked by maggots, and thus rendered more attractive. Baits were found to be much more attractive in the sun than in the shade. The best bait for house-flies is a mixture of casein, banana, any sweet substance, and water. Formalin in water (about 1 : 13) is apparently the best poison (excluding scheduled poisons) to use against house-flies.

### *Bilharzia Disease in Egypt.*

Dr. R. T. Leiper gave an account of the later results obtained by the War Office Bilharzia Commission in Egypt. After sketching the conditions in a village where 91 per cent. of the schoolboys were found to be infected with Bilharzia, Dr. Leiper stated that the Commission had proved the occurrence of two species of Bilharzia, the chief characters of which he pointed out with the help of lantern illustrations. The egg of

Digitized by Google

*Bilharzia haematobium* is terminal-spined, and the cercariæ are found in the fresh-water molluscs, *Bullinus contortus* and *B. dybowski*. The egg of *Bilharzia mansoni* is lateral-spined, and the cercariæ occur in *Planorbis boissyi*. From these molluscs the cercariæ escape, and were proved to enter experimental animals through the skin as well as through the mucous membrane of the mouth.

*Protozoa and Disease.*

Dr. Helen Pixell-Goodrich gave an account of the amœbæ parasitic in man, namely, *Entamoeba histolytica*, the specific cause of amœbic dysentery, from the large intestine; *E. gingivalis*, from the mouth; and *E. coli*, a harmless species, feeding on the contents of its host's intestine. Dr. Pixell-Goodrich devoted special attention to *E. gingivalis* in relation to pyorrhœa, but although this amœba occurs so commonly in these lesions, it was not considered to be the cause of the disease. The morphological similarity of the trophozoites of *E. gingivalis* and *E. histolytica* was pointed out, and the large characteristic inclusions of the former were held to be the nuclei of lymphocytes.

Dr. T. Goodey's paper dealt with the results of observations by Mr. Wellings and himself on *E. gingivalis*, which they found in the mouths of both young and old persons wherever there was accumulation of food débris. They concluded that there is nothing to show that the organism is in any way causally connected with pyorrhœa, the food bodies being nuclear fragments of decomposed salivary corpuscles.

Dr. Annie Porter gave an account of observations by Dr. H. B. Fantham and herself on the flagellate protozoa associated with dysentery, with special reference to cases from Gallipoli. *Trichomonas hominis* has been found in cases of severe diarrhœa at Salonica; prophylaxis is directed to the prevention of contamination of food or water by infected material and by possible insect carriers and rodents (similar Trichomonads occur in rats, mice, and rabbits), and to the isolation of human "carriers." Cases of Tetramitus diarrhœa have been found among patients from Egypt, Gallipoli, and Salonica. *Giardia (Lamblia) intestinalis* was found to be the commonest flagellate in the stools (3800) of the soldiers examined, and in some cases occurred in enormous numbers; one stool was estimated to contain 14,400,000,000. Giardia derived from man is pathogenic to kittens and mice, producing erosion of the intestinal cells. Rats, mice, and cats can act as "reservoirs," and by contaminating the food and drink of man may spread the organism.

*War and Eugenics.*

Mr. Hugh Richardson stated the case for the institution of an inquiry into the after-effects of war on population. He pointed out the nature of the evidence available or to be sought, the statistical methods to be employed, and, after referring to the various and dubious theories held in the past, indicated some of the problems which seemed capable of solution. Subsequent speakers—Dr. Chalmers Mitchell, Dr. Doncaster, Dr. Tocher, and Prof. MacBride—were emphatic in supporting the case for an impartial inquiry and for the collection and preservation of statistical information by the Registrar-General, the Army recruiting staff, school medical services, and other agencies.

Dr. F. A. Dixey exhibited and commented upon a series of insects collected on the way to and from and in Australia in 1914. Mr. Heron-Allen exhibited lantern-slides illustrating the mussel fishery and the life of Alcide d'Orbigny at Esnandes.

The Friday afternoon was devoted to a visit to the Dove Marine Laboratory at Cullercoats, the members being taken over the laboratory and aquarium by the director, Prof. Meek. J. H. ASHWORTH.

## ENGINEERING AT THE BRITISH ASSOCIATION.

MR. GERALD STONEY devoted his presidential address to a review of some of the errors committed in the past by masters and men in the engineering industry. An abridgment of the address appears elsewhere in this issue of NATURE.

After the address a paper on "Limit Gauges" was read by Dr. R. T. Glazebrook, director of the National Physical Laboratory. This subject has been forced upon the attention of the whole engineering world by its importance in the manufacture of munitions. The greatly increased scale of manufacture necessitated the production of an enormous number of gauges, both for workshop use and for testing. The National Physical Laboratory has acted as the checking authority for the correctness of the gauges employed by the Government inspectors. Dr. Glazebrook first described the principles of limit gauging and then the various methods and apparatus evolved for dealing with the problem at the National Physical Laboratory.

A paper on "The Principle of Similitude in Engineering Design" was read by Dr. T. E. Stanton, who discussed the possibilities and difficulties of obtaining accurate information for the design of structures, ships, aeroplanes, propellers, etc., from tests made on small models.

The late Mr. Leslie Robertson, who was lost on the *Hampshire*, had promised to read a paper on the work of the International Standards Committee. Mr. le Maistre, who has succeeded him as secretary of the committee, took over the task, and read an interesting paper on "Standardisation and its Influence on the Engineering Industries."

Mr. H. T. Newbigin described the *raison d'être* of the Michell type of bearing. Already in common use for thrust bearings, it is now being experimentally applied to journal bearings.

Prof. W. M. Thornton discussed "The Influence of Pressure on the Electrical Ignition of Methane," and described experiments showing that, as the pressure is gradually increased, the energy in the spark necessary to cause ignition increases in a stepped, discontinuous manner.

Prof. W. H. Watkinson described some tests showing that Diesel engines could be worked satisfactorily with compression pressures considerably lower than those usually employed.

Prof. G. W. O. Howe read a paper on "The Calculation of the Capacity of Aerials, including the Effects of Masts and Buildings." Papers on this subject were read by the author at the Sydney and Manchester meetings; in the present paper the subject is carried further, and a number of numerical examples and experimental results are given which fully confirm the method of calculation.

Mr. McLachlan described the results of some experiments on a Poulsen arc, to determine the best magnetic field strength to employ for maximum output and for maximum efficiency.

The only research committee that reported at length was that on "Complex Stress Distribution," in connection with which Dr. Stanton exhibited a model of a new machine in use at the National Physical Laboratory for subjecting a specimen to a rapidly reversing combination of bending and twisting.

The last day of the meeting was devoted to a joint discussion with the Chemical Section of the report of the Committee on Fuel Economy.

## THE BRITISH ASSOCIATION AT NEWCASTLE.

### SECTION G.

#### ENGINEERING.

OPENING ADDRESS (ABRIDGED) BY GERALD STONEY, B.A.I. (DUB.), F.R.S., M.INST.C.E., PRESIDENT OF THE SECTION.

AT times such as these the mind naturally turns to problems to be considered both at the present time and after the war, and in considering such problems a review of some of the errors committed in the past is most necessary. Such a review enables methods which should be adopted both now and in the future to be considered. As this is an address to the Engineering Section of the British Association for the Advancement of Science, only such problems will be considered as affect engineering and its allied industries.

One thing which has handicapped our industries is the reluctance of firms to utilise highly educated labour or to adopt scientific methods. In looking round the industries of the district one is struck by the small number of men who have undergone a thorough scientific training at one of the universities or at one of the leading technical colleges, and who occupy a prominent place in the firms in this district.

The general complaint is that university and college men are too theoretical and not practical. It is the usual thing for a bad workman to blame his tools, and is it not because employers do not know how to make use of such labour that they utilise it to such a small and imperfect extent?

Things are very different in some other countries with which we have competed in the past, and with which there will be in all probability still fiercer competition in the future. There we find the fullest use made of highly educated scientific labour.

How many engineering firms in this district have a skilled chemist on their staff, and what percentage of these pay him a decent salary? And how many heads of firms have sufficient chemical knowledge to appreciate the work and utilise the services of such a man? because unless there is appreciation of the work done by such a man his services are useless and he becomes discouraged, generally finding himself up against the blank stone wall of there being no appreciation of his services, and yet chemical problems are continually cropping up in engineering work. There is the question of the supply of materials; as a rule the manufacturer trusts to the name of the contractor and assumes that he gets materials of the composition and purity he ordered. Every now and then something goes wrong and the question arises, Why? Without a chemist to analyse the material it is often most difficult to say. Apart from this question of the analysis of raw or partly manufactured materials received, there is the chronic question as to the mixtures of the metals in both the metal and brass foundry, and large economies can be effected by systematic analyses.

Another direction in which scientific labour is invaluable is in seeing that instruments are in proper order, and that tests are accurately carried out. Tests carried out with inaccurate instruments and without proper scientific precautions to see that they are accurate and trustworthy are worse than useless, and, in fact, most misleading and dangerous, as entirely untrustworthy inferences may be drawn from them and far-reaching troubles caused in the future. Under scientific supervision arrangements are made to avoid such troubles and get trustworthy results which can be depended on for future designs.

What is the case with pressure gauges and the measurement of pressure applies, of course, to all other instruments and measurements. In most works it may be said with sorrow that the only moderately accurate measurements that can be made are those of dimensions and weight. It is only by accurate testing of existing plant that trustworthy deductions can be drawn enabling safe progress to be made in future designs.

One of the great things which helped forward the steam turbine in the early days was accurate and full testing of each plant as soon as it was completed and before it left the works. The late Mr. Willans was probably the first, or one of the first, to recognise the importance of accurate testing of steam plant, and the success his well-known engine had was largely due to this. From the earliest days of the steam turbine Sir Charles Parsons recognised the necessity of such testing, and the test-house has always been a prominent feature of Heaton Works. And then in the higher ranks of an engineering works it requires a scientific mind to draw safe conclusions from tests carried out and to see in what directions progress can safely be made. Such methods have enabled the steam turbine during the writer's acquaintance with it, now extending over some twenty-eight years, to grow from 50 horse-power to some 45,000 or more in each unit, and the steam consumption to be reduced from 40 lb. per h.p.-hour to about 7½ lb., or less than one-fifth.

And closely allied to such work in engineering works is the general question of scientific research, and here a trained scientific mind is of the utmost importance to see that trustworthy results are obtained and to make true logical deductions from those results. Without suitable training a man is liable to be unable to grasp all the conditions of an experiment and to make deductions from the data obtained which are totally unjustified and often lead to most disastrous results in the future.

Such research is generally carried out in four places —engineering works, private laboratories, engineering colleges, and national laboratories. The first has already been dealt with. The second is of comparatively small importance in practice.

As regards the third, a great deal of good work has been done in engineering colleges, often under great difficulties for want of plant and money, and it is greatly to the credit of our professors and others that they have succeeded in doing so much with the very inadequate appliances at their disposal, and handicapped for want of funds. How inadequate their income is can be understood when it is remembered that Leipzig University alone has an annual income from the German Government of 100,000*l.*, as against a total Government grant to *all* the universities here of about 45,000*l.*, or less than half.

Of national laboratories we have only one, the National Physical Laboratory at Teddington, and here again the support given to it is totally inadequate. The total income from all sources last year was only 40,000*l.*, and of this 23,000*l.* was charges for work done, such as testing meters and other instruments and similar commercial work; the Government grant is only 7000*l.* a year, and besides this 7500*l.* was received for experiments in connection with aeronautics, which is really war work. The balance was made up of subscriptions, grants from technical societies, and miscellaneous receipts. Compare this with the German equivalent, the Reichsanstalt of Berlin, which has an income of 70,000*l.* a year from the Government, or ten times that given to our N.P.L. The Bureau of Standards, the similar institution in the U.S.A., has a Government grant of 140,000*l.*, or twenty times ours. In the Civil Service Estimates there is an allowance of 40,000*l.* for research, an increase of 15,000*l.* over that allotted last year. The total estimates are more

Digitized by Google

than 20,000,000l., so that less than one-fifth per cent. is allotted to research.

It is difficult to realise what benefits might be gained by investigations which could be carried on by the N.P.L. if only sufficient funds were available, and of what importance they might be to industry at large. One example may suffice. Some time ago the Reichsanstalt carried out a most complete set of tests on a certain class of machine, an investigation which must have cost several thousands of pounds sterling, apart from the time it occupied. The results of this investigation are available to German manufacturers of this machine, and just before the war preparations were being made to take advantage of this, and from figures stated a large extra economy was expected. This, of course, would enable them, provided the cost of manufacture was not too high, to have an enormous advantage over such machines manufactured without this special knowledge. The Institution of Mechanical Engineers saw the importance of this problem and appointed a Research Committee to deal with the matter, but the first question met with is that of finance. Should this be the case in a wealthy country such as this that depends on its manufactures for its very existence? And that such an investigation is required is obvious from the fact that the designs of no two independent manufacturers of this machine in this country agree among themselves. Of course, each claims his is the best, but this cannot be so.

Investigations in engineering shops do not meet such a case. The question of finance has to be carefully watched, and as soon as results sufficiently good are obtained they are generally accepted, and in any case the problem is rarely thrashed out to the bottom, an almost universal defect in commercial research work. Without the help of the National Physical Laboratory the position of the aeroplane in this country would be very different from what it is, and what has been done for the aeroplane requires to be done in many other directions.

But what firm here would do what has been done in the commercial synthesis of indigo, on which it is said that seventeen years' work and more than 1,000,000l. have been spent by one firm alone abroad? Here in chemical investigations and manufactures the Government refuses even to give the help of allowing cheap alcohol to be obtainable, and much of such work is impossible in this country on that account, as in many cases methylated and denatured alcohol are not suitable. Recently under pressure the restrictions have been somewhat relaxed by the Government, but many manufacturers have found that the privileges granted are so tied up with red tape that the concessions are practically useless.

I am sorry to say the employer does not look after the welfare of his workmen as he might. In a small factory the head of the firm, as a rule, knows all the leading men among the workmen, many of them having been with him for years. As the place grows he loses touch with his men, and as an actual fact knows fewer of those under him when he has 1000 or more employees than he did when he had 400 or under. This state of things gets worse when the place is turned into a limited liability company, as nearly all large places are at present. The result is that a most deplorable state of things has come to pass. The workman says, "Put not your trust in employers"; the master says, "Put not your trust in workmen"; and the official who is between the master and the workman says, "Put not your trust in either."

It is difficult to say what is to be done to remedy this state of things, but one cannot help feeling much might have been done in the past to have prevented such a regrettable state of affairs as there is at present. Much of this trouble might have been avoided if employers had shown more consideration for the welfare of their workmen.

With the growth in strength of the Trades Unions, which at first were for the legitimate object of seeing that the workman got fair play, and providing out-of-work and old-age benefits, etc., has grown up a system of Trades Union officials who live by agitation, and whose jobs would be gone if there were no supposed grievances to agitate about. These men keep the labour world in a constant state of agitation, and make the employers' and officials' existence a burden to them by constant demands of all sorts, many of them utterly impracticable and unfair. When they cannot agitate against the employer they agitate against another Trades Union, and thus endless disputes spring up on the demarcation of work. Some of the worst strikes in the past have been due to disputes between two Trades Unions.

Unless something can be done to bring master and man together and make both work for the common good, English trade must inevitably go down, and the supremacy that England has in the engineering of the world will come to an end.

Nothing ever was a truer statement than that recently made by Lord Joicey that this country, unless it produces as cheap as, or cheaper than, other countries, cannot in the long run keep her trade, and this is true in spite of any tariff walls which may be set up. And if the present state of affairs is maintained of unscientific management and obsolete machinery, combined with limitation of output and high wages, or, in other words, high cost of production, we must, sooner or later, go to the wall.

What is really wanted is common honesty and common sense on both sides, for one side is as bad as the other at present.

Apart from the considerations set out above, combinations among the firms employed in any one trade are most essential for the well-being of that trade. It is by such combination that much of the progress made of late years by our competitors has been effected. Some of these combinations have been international, and at least two such in the engineering trade were so before the war. These now, of course, are, and it is expected will be after the war, confined to the Allied and possibly to neutral countries, but such combinations, whether among all the engineering firms in one district or among firms employed in one particular trade, to be successful must be worked fairly to all members, and the larger firms must not override the smaller, as, it is regrettable to say, has been done in combinations of employers in some districts. For example, in a district where there is one firm very much larger than any of the others, it is not unknown for it to act the bully and insist on everything being done as would suit its requirements, regardless of the rights of others. And, further, such combinations are, unless directed by men with broad minds and able to take a wide view of things, liable, especially in case of emergency, to do much harm.

If the armament ring in this country had taken such a view when it was found what an enormous supply of munitions was required, it is doubtful if there would have been such a shortage as there has been. Hundreds of firms were willing and anxious to help in the production of munitions, but when they offered their services they were met in many cases with a blank refusal, and in all cases with little encouragement. And when, under pressure from the Government, the ring accepted outside help, in many cases the conditions imposed on the sub-contractors were unfair in the extreme, apparently the whole idea of the ring being to make all the profit they could out of the troubles of the Empire. It has been just as difficult to persuade the armament ring to give up

Digitized by Google

what they thought was their monopoly and to bring in outside works to help in the production of munitions as it has been to persuade the Trades Unions to forgo trade customs and to enable outside sources of labour to be employed, such as women and other unskilled labour. But both have had to do it. In other words, "dilution of works" has been as difficult to effect as "dilution of labour," and the position both of the armament ring and of the workman would have been very different if they had consented freely to it when it became obviously necessary for the safety of the Empire.

The necessities of research work have already been dealt with, and by the pooling of such research work enormous advantages in any one trade could be obtained. Such pooling of information has been effected with most beneficial results, especially in the chemical trade abroad. Any workable scheme which would enable this to be done and get over the jealousies between one firm and another would be of enormous benefit to the trade in general.

Another thing that must not be lost sight of is the urgent need of improving our educational system. It is little short of a disgrace that the older universities are closed to those without a knowledge of Latin and Greek.

Languages are of the greatest importance to an engineer—not dead languages, but living ones. And these should be properly taught, so that the student should be able not only to read and write them, but also to speak and understand them when spoken. It is quite a different knowledge of a language to be able to read, write, speak, or understand it. Many people can read a language without being able to write, speak, or understand it when spoken, and conversely it is not uncommon to meet people who can speak and understand a language without being able to any large extent to read or write it. And it is only in living languages that a man is trained to speak and understand a language.

Why is it that we are so wedded to the dead languages? There is, of course, the tradition that such are necessary for a liberal education, and there is the argument that modern languages are not so good a training for the mind. Granted that they are not quite so good from the point of view of learning to read and write them, does not the fact that they can also be taught as a living language to be spoken and understood make them on the whole the best educationally for a man? This is entirely apart from the fact that modern languages are useful and ancient useless to the man in commercial work. There is, of course, bitter opposition from that most conservative man, the schoolmaster, and one great reason is that it is much easier and cheaper to get a man to teach Latin and Greek than modern languages which have to be taught orally. The teaching of Latin and Greek as they are usually taught has been standardised to the last degree, and as a result they can be taught by the "semi-skilled" man, and a skilled" man is not necessary, to use engineers' phraseology. In fact. the teaching of Latin and Greek is a pure "repetition job." At the same time, no education is complete unless science is combined with languages, and also literature, and here lies one great danger of modern technical education.

After the boy has left school and enters the shops more facilities should be given to enable him so-called "trade secrets," but an immense deal of information can be given to an apprentice without doing so.

Evening classes are all very well in their way, but more facilities should be given for the diligent apprentice to attend day classes, and this can be arranged in various ways if the employer has a will to do it. A thing that at present often prevents boys desirous of educating themselves getting on is the fact that overtime is allowed as soon as a boy is eighteen, and often he is compelled to work overtime regardless of classes that he ought to be attending.

It is important to remember that the boy of to-day is the man of to-morrow.

One complaint is that after a lot of trouble is taken about a boy he leaves after a few years and goes to another employer. The good of the trade in general must be considered, and a man who has had experience of various classes of work is generally a much more valuable man than one whose knowledge is confined to one class only. In any case, the other employer gets the benefit of what has been done by the first, and thus the trade in general benefits.

It is realised that this is a very imperfect review of things as they are at present, but if this address induces all classes engaged in engineering to consider how things can be bettered the author feels that a part, at all events, of his object has been attained.

## *UNIVERSITY AND EDUCATIONAL INTELLIGENCE.*

CAMBRIDGE.—Notice is given of the forthcoming appointment to the George Henry Lewes studentship in physiology. The object of the studentship, the annual value of which is 200*l*. and is tenable for three years, is to enable promising students to devote their whole time to physiological research. Candidates are requested to send a short statement of their qualifications to Prof. J. N. Langley, the Physiology School, Cambridge, by November 18.

LONDON.—At a meeting of the Senate held on October 18, the Vice-Chancellor (Sir Alfred Pearce Gould) being in the chair, the following doctorates were conferred:—*D.Sc.* (*Engineering*), Mr. E. H. Salmon, an internal student, of the East London College, for a thesis entitled "Columns." *D.Sc.* (*Economics*), Mr. P. Bandyopadhyay, an internal student, of the London School of Economics, for a thesis entitled "Public Administration in Ancient India." *D.Sc.* (*Physiology*), Miss D. J. Lloyd, an external student, for a thesis entitled (*a*) "The Osmotic Balance of Skeletal Muscle," (*b*) "The Relation of Excised Muscle to Acids, Salts, and Bases."

OXFORD.—The reports for the year 1915 of the curators of the Botanic Garden and of the Department of Botany have just been published. They contain long lists of contributors, both public and private, of specimens and other material for study to both institutions. To most of those who have sent donations to the garden a return has been made in kind. Many interesting plants have flowered in the garden during the past year. In the Department of Botany lectures have been given by the Sherardian professor and Messrs. A. H. Church and W. E. Hiley. Practical

MISS G. J. SANDERS, formerly principal of the Low-thorpe (Massachusetts) School of Horticulture and Landscape Architecture for Women, has been appointed principal of the Swanley Horticultural College.

A PAMPHLET issued by the Bradford Education Committee describing the courses in chemistry and dyeing held at the Technical College in that town is symptomatic of the altered outlook towards the various branches of the chemical profession brought about by the world-war. These college courses are, in the first place, arranged to meet the growing requirements of the local dyeing industry. Together with the study of colouring matters, practical instruction is given in the art of dyeing in a dye-house with full-sized machinery combined with a finishing plant for completing the commercial treatment of cloth. As in many other technical colleges, there is an entrance examination, in which English and mathematics are compulsory. Special stress is laid on the fact that a sound secondary education up to the age of sixteen or seventeen is a preliminary asset of the greatest importance. The combined course in chemistry, dyeing, and the allied subjects extends over a period of four years. A similar course has been devised for those taking up chemical work in other industries, such as in oil and soap works, or in metallurgy or gas engineering. Both these courses include a certain proportion of mechanics and engineering bearing specially on chemical industries. Students passing satisfactorily through either of these courses receive the college diploma, but the associateship of the college is reserved for those who have had one year's practical experience subsequent to the award of the diploma, and who have submitted a thesis on some previously approved subject. The ultimate object of the curricula of this college is to turn out practical chemists, dyers, and pharmacists, and that these qualifications are appreciated by manufacturers is seen from the encouraging list of appointments secured by the alumni.

AN appeal on behalf of the Endowment Fund of the School of Oriental Studies at the London Institution has been issued by an influential committee of which Lord Curzon is chairman. The objects of this new institution are three in number:—(1) To provide a place where the Englishmen who will presently be engaged in governing or garrisoning the Oriental and African parts of the Empire may learn the languages and study the literature, the religions, and the customs of the peoples with whom they will be brought into contact; (2) to offer a training to those who are about to proceed to the same countries to take part in commercial enterprise or avocations; (3) to furnish in the capital of the Empire a meeting-ground and focus for the scholars of the East of all nationalities on their visits to this country. Evidence has been accumulating in recent years that the training of our Civil Servants and officers in the languages and modes of thought of Oriental peoples falls short of the ideal which we ought to have in view. In the new relations that will develop when the war is over there must be a higher standard of efficiency in these respects if our rule is to continue to commend itself to those with whom we are brought into relations. Information has been received that important steps are already being taken in Germany to give a higher education to Germans about to proceed to the East. Provision will be made in the new London school for all the more important languages of the Near, Middle, and Far East, and of Africa. The committee desires to raise an endowment fund of 150,000*l*., towards which they have now as a result of a preliminary appeal about 10,000*l*. Donations and subscriptions may be paid to the head office or to any branch of the London County and Westminster Bank, or to the secretary of the executive of the appeal committee at the School of Oriental Studies, Finsbury Circus, E.C. The governing body of the school has appointed Dr. E. Denison Ross, C.I.E., to be its director, and he will take up his work almost immediately. Dr Ross has travelled extensively in the East. Among his numerous works is the "Tarikh-i-Rashidi," a history of the Moguls of Central Asia.

A SERIES of resolutions referring to the claims of humanistic studies to scientific attention was adopted a couple of months ago by a conference representing the Classical, English, Geographical, Historical, and Modern Language Associations (see NATURE, September 7, p. 23). The committee of the Association of Public School Science Masters has just expressed agreement with the principles of education stated in the resolutions; and in answer to an invitation to make a statement with regard to education in the natural sciences, it has sent the following to the chairman of the conference:—"Natural science in education should not displace the 'humanistic' studies, but should be complementary to them. In this capacity natural science meets two needs in particular:—(1) *Search for Truth*: Imaginative power indicates new fields in which further knowledge of truth may be revealed; its subsequent establishment depends on accurate observation, with constant recourse to nature for confirmation. The one aim of natural science is, in fact, the search for truth based on evidence rather than on authority. Hence the study of the subject implies accurate observation and description and fosters a love of truth. The special value of Natural Science in the training of Mind and Character lies in the fact that the history of the subject is a plain record of the search for Truth for its own sake. (2) *Utility*: There are certain facts and ideas in the world of natural science with which it is essential that every educated man should be familiar. A knowledge of these facts assists men (*a*) to understand how the forces of nature may be employed for the benefit of mankind; (*b*) to appreciate the sequence of cause and effect in governing their own lives; and (*c*) to see things as they really are, and not to distort them into what they may wish them to be. It is the business of Natural Science in education to bring this knowledge within the range of all." The statement is signed by Prof. H. H. Turner, president of the Association of Public School Science Masters, and by Mr. A. Vassall, chairman of committee. Probably arising out of the conference referred to above, a Council of Humanistic Studies has been constituted, comprising representatives of the British Academy, in addition to the five associations mentioned above. Its object is to watch educational developments in the interests of the studies represented by these bodies and to co-operate, if possible, with the representatives of natural science. The president is Lord Bryce, and the chairman Sir Frederic Kenyon, to whom communications may be sent at the British Museum.

## SOCIETIES AND ACADEMIES.

### LONDON.

**Geological Society**, June 28.—Dr. Alfred Harker, president, in the chair.—Dr. A. Smith **Woodward**: A new species of Edestus from the Upper Carboniferous of Yorkshire; with a geological appendix by J. Pringle. The fossil confirms the interpretation of Edestus as a row of symphysial teeth of an Elasmobranch fish. The row of eight bilaterally symmetrical teeth, fused

Digitized by Google

together, occurs at the tapering end of a pair of calcified cartilages, which evidently represent a jaw. An imperfect detached tooth probably belongs to an opposing row. The teeth are large compared with their base, and the serrated edges have been worn during life. Small Orodont teeth of the form named Campodus are scattered in the shale near the jaw. Markings on the Edestus teeth themselves suggest that they have been derived from the Campodus type of tooth. The specimen was obtained from shale below the Rough Rock, in the upper part of the Millstone Grit, at Brockholes, near Huddersfield.—A. **Holmes**: The Tertiary volcanic rocks of Mozambique. With the exception of a coastal belt of Cretaceous and Tertiary sediments, flanked on the west by later Tertiary volcanic rocks, the territory consists of a complex of gneisses and other foliated rocks, intruded upon by granites belonging to at least two different periods. From Fernão Vellosa Harbour to Mokambo Bay the junction of the sedimentary formations with the crystalline complex is faulted, and the volcanic rocks are distributed on each side of the fault. The lavas are of post-Oligocene age, and are the result of fissure-eruptions, the feeding channels being exposed as small dykes that penetrate the underlying rocks. The prevailing lavas are amygdaloidal basalts. An andesite dyke of later date occurs near the Monapo River. In the north, near the Sanhuti River, picrite-basalt, basalt, phonolite, and sölvsbergite have been found, and related lavas occurring elsewhere in the area are tephritic pumice and ægirine-trachyte. The "alkali" series can be closely matched by the lavas of Abyssinia, British East Africa, Réunion, and Teneriffe. The amygdaloidal basalts of the "calc-alkali" series are similar to those of the Deccan, Arabia, and East Africa, and also to those (of late Karroo age) occurring in South Africa and Central Africa. Each of the series was probably evolved by a process of differentiation acting on a parent magma. From the composition of the amygdale minerals it is deduced that the parent magma of the "alkali" series was rich in carbon dioxide and under-saturated in silica; whereas that of the "calc-alkali" series was rich in water and over-saturated in silica. The rádio-activity of the lavas indicates that the depth from which the parent magma came was probably between thirty-three and forty-four miles from the earth's surface.

**Royal Microscopical Society**, October 18.—Mr. E. Heron-Allen, president, in the chair.—Dr. Helen Pixell **Goodrich** and M. **Moseley**: Certain parasites of the mouth in cases of pyorrhœa. After a general description of the pathological changes in gum tissues resulting from pyorrhœa, illustrated by sections of normal and infected jaws, a detailed account of *Entamoeba gingivalis*, Gros, was given, followed by notes on Trichomonas and the interesting complex Leptothrix colonies, which give rise to the tartar. Of these parasitic organisms only the Leptothrix colonies were considered by the authors as likely to be the cause of the disease.

## PARIS.

**Academy of Sciences**, October 2.—M. Camille Jordan in the chair.—E. **Picard**: Functions of two complex variables remaining invariable by substitutions of a discontinuous group.—G. **Bigourdan**: The declaration of Louis XIII. relating to the first meridian. The text of the declaration, dated July 1, 1634, is given in full. The position chosen had no scientific basis.—G. **Bigourdan**: The propagation of the sound of the cannonade at the front to great distances. There is evidence that the sounds heard are not propagated through the air, but through the soil.—H. **Douvillé**: The Cretaceous and the Tertiary in the neighbourhood of Thones (Haute Savoie).—J. **Meunier**: The detection of small quantities of selenium; distinction from arsenic. Selenium may cause error in the Marsh test for arsenic when present in minute traces only. A scheme for examining the deposit is given, by means of which selenium can be detected in the presence of arsenic.—P. **Garrigou-Lagrange**: Luni-solar action and temperature.—J. **Amar**: The technique of the sense education of men without limbs or sight. Details of the methods and apparatus used in the education of the sensibility of mutilated limbs, and of the sense of touch in the blind.—L. **Camus**: Vaccinal immunity resulting from intravascular injections of vaccine.

## WASHINGTON, D.C.

**National Academy of Sciences** (Proceedings No. 9, vol. ii., September 15).—J. **Loeb**: The mechanism of diffusion of electrolytes through animal membranes. For the diffusion of certain electrolytes through animal membranes there is required, besides the osmotic pressure, a second effect, called the "salt effect," upon the membrane. This consists probably in an ionisation of the protein molecules of the membrane.—F. G. **Pease**: The rotation and radial velocity of the spiral nebula N.G.C. 4594. The radial velocity is +1180 km., in good agreement with the values found by Slipher. The linear velocity of rotation at a point two minutes of arc from the nucleus is more than 330 km.—F. H. **Seares**: A simple method for determining the colours of the stars. The method suggested consists in determining the ratio of exposure-times which is necessary to produce photographic and photovisual, or, more briefly, blue and yellow, images of the same size.—H. **Shapley**: Studies of magnitudes in star clusters. III. The colours of the brighter stars in four globular systems. It is concluded that in all the clusters examined, and probably in all globular clusters, the volumes of the bright red stars are very great in comparison with the stars that are fainter and relatively blue.—Janet T. **Howell**: The effect of an electric field on the lines of lithium and calcium. Lithium and calcium were examined, both for longitudinal and transverse effects.—A. B. **Coble**: A proof of White's porism.—J. P. **Iddings** and E. W. **Morley**: A contribution to the petrography of the Philippine Islands. Six detailed analyses are given of rocks from Luzon, P.I.—W. O. **Fenn**: Salt antagonism in gelatine. The experiments on gelatine support the hypothesis that anions antagonise kations in their effects upon organisms. The hypothesis here developed resembles that of Clowes except that it requires that NaCl should antagonise any electrolyte which has either a strong anion or a strong kation. The point of maximum antagonism is an isoelectric point at which the amount of alcohol needed for precipitation is at a minimum, and the aggregation or amount of precipitation is at a maximum.—W. O. **Fenn**: Similarity in the behaviour of protoplasm and gelatine. A close analogy to Osterhout's experiments on the electrical resistance of Laminaria is found in gelatine (plus NaOH), if we assume that the effect of time in the Laminaria experiments is to increase the concentrations of the salts in the cells of the tissue.—W. E. **Milne**: Certain asymptotic expressions in the theory of linear differential equations. Formulas more precise than those previously obtained by Birkhoff are given.—H. B. **Fine**: Newton's method of approximation. A condition is given under which Newton's method of approximation for computing a real root of an equation, and the extension of this method used in computing a root of a system of equations, will with certainty lead to such a root or solution.

## THE BRITISH OXYGEN COMPANY LTD.

**Works** for the production of **Oxygen** and other gases in **London** (Westminster, Greenwich and Stratford), **Birmingham, Cardiff, Wolverhampton, Manchester, Birkenhead, Sheffield, Newcastle-on-Tyne, Glasgow,** and **Sydney, N.S.W.**

**The Company** was formed in 1886 as Brin's Oxygen Company to develop means for the production of Oxygen on an industrial scale.

**The Company** is not only the acknowledged pioneer of the Oxygen Industry, but possesses the largest organisation in the World for the production and distribution of that gas.

**The Company** also manufactures and supplies in cylinders, NITROGEN, HYDROGEN, CARBONIC ACID, and other gases.

**The Company** has developed an extensive engineering business, and has specialised in the design and manufacture of Plant for the production and separation of gases by liquefaction, electrolysis, and other methods.

**The Company** is the exclusive manufacturer in the United Kingdom of apparatus for metal cutting by Oxygen, and also manufactures well-known types of gas Regulators, Oxy-Acetylene and other blowpipes, and a large variety of apparatus for use with gas cylinders.

For illustrated price lists and full particulars application should be made to any of the Company's Works or to the Head Office, **Elverton Street, Westminster, S.W.**

## SECOND-HAND DEPARTMENT

**Microscopes, Telescopes, Spectroscopes, etc.,**
**by the best makers at moderate prices.**
*Instruments Bought, Taken in Exchange, or Sold on Commission.*

**JOHN BROWNING, 146 STRAND, LONDON.**

## ROCK-FORMING MINERALS

**in great variety and of all sizes.**

**MINERALS FOR ECONOMIC PURPOSES OF ALL KINDS.**

Minerals for all Scientific Work can be supplied by

**JAMES R. GREGORY & Co., Mineralogists, &c.,**
**139 FULHAM ROAD, SOUTH KENSINGTON, S.W.**

Telegrams: "Meteorites, London." Telephone: Western 2841.

## LIVING SPECIMENS FOR THE MICROSCOPE.

Volvox, Spirogyra, Desmids, Diatoms, Amœba, Arcella, Actinosphærium, Vorticella, Stentor, Hydra, Floscularia, Stephanoceros, Melicerta, and many other specimens of Pond Life. Price 1s. 6d. per Tube, Post Free. Helix pomatia, Astacus, Amphioxus, Rana, Anodon, &c., for Dissection purposes.

**THOMAS BOLTON,**
25 BALSALL HEATH ROAD, BIRMINGHAM.

## MARINE BIOLOGICAL ASSOCIATION OF THE UNITED KINGDOM.

**THE LABORATORY, PLYMOUTH.**

The following animals can always be supplied, either living or preserved by the best methods:—

Sycon; Clava, Obelia, Sertularia; Actinia, Tealia, Caryophyllia, Alcyonium; Hormiphora (preserved); Leptoplana; Lineus, Amphiporus, Nereis, Aphrodite, Arenicola, Lanice, Terebella; Lepas, Balanus, Gammarus Ligia Mysis, Nebalia, Carcinus; Patella, Buccinum, Eledone, Pectens Bugula, Crisia, Pedicellina, Holothuria, Asterias, Echinus, Salpa (preserved), Scyllium, Raia, &c., &c.

For prices and more detailed lists apply to Biological Laboratory, Plymouth. THE DIRECTOR.

## WATKINS & DONCASTER,

**Naturalists and Manufacturers of**

## CABINETS AND APPARATUS

*FOR COLLECTORS OF INSECTS, BIRDS' EGGS AND SKINS, MINERALS, PLANTS, &c.*

N.B.—For excellence and superiority of Cabinets and Apparatus, references are permitted to distinguished patrons, Museums, Colleges, &c.

**A LARGE STOCK OF INSECTS, BIRDS' EGGS AND SKINS.**

**SPECIALITY.—Objects for Nature Study, Drawing Classes, &c.**

**Birds, Mammals, &c., Preserved and Mounted by First-class Workmen true to Nature.**

**All Books and Publications (New and Second-hand) on Insects, Birds' Eggs, &c., supplied.**

**36 STRAND, LONDON, W.C.**
(Five Doors from Charing Cross.)
*FULL CATALOGUE POST FREE*

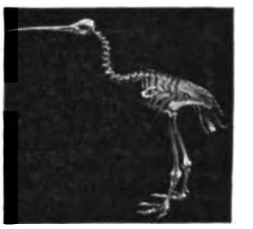
**FOR ALL KINDS OF EDUCATIONAL**

## Mineral Material,

**COMMON ORES, and SELECT CRYSTALLIZED SPECIMENS, at ALL PRICES.**

**G. H. RICHARDS & CO.,**
Dealers in all kinds of British and Foreign Mineral Specimens.
*PRICE LISTS FREE.*
**48 Sydney Street, Fulham Road, South Kensington, London, S.W.**

**SKELETONS & SKULLS**
Specimens and Preparations for Teaching
BIOLOGY & ZOOLOGY
and for Museums.
*Lists on Application.*
**EDWARD GERRARD & SONS**
*Osteologists and Taxidermists.*
NATURAL HISTORY STUDIOS
**61 College Place,**
**Camden Town, London.**



Collections in Polished Deal Boxes.

## MINERALS, ROCKS, FOSSILS.

25 Specimens, 5/6; 50 do., 10/6; 100 do., 21/-; 200 do., 42/-.
50 Coal Measure Rocks and Fossils, 12/6; do., larger, 15/-.

*Inspection invited of a large stock of Minerals, Rocks, Fossils, and Microscopic Objects. Specimens sent on approval.*

**Prospectors' Sets, Blowpipe Cases, Cabinets, Geologists' Hammers, Card Trays, Glass-Capped Boxes, Models of Crystals, and all Apparatus for Mineralogists and Geologists.**

**ROCK SECTIONS to Order at 1/6 each.**

NEW CATALOGUES POST FREE.

**RUSSELL & SHAW, 38 Ct. James Street, Bedford Row, London, W.C.**

*NOTICE.—Advertisements and business letters for "Nature" should be addressed to the Publishers; Editorial Communications to the Editor. The telegraphic address of "Nature" is "Phusis," London. Telephone—Gerrard, 8830.*

**Microscopes**
(including Petrological and High-Power Binocular),
**Objectives**
(including Apochromatic),
**Microtomes, Optical Lanterns,**
**Photomicrographic Apparatus, etc.**

**WHITE GLASS MICRO. SLIPS.** Thickness 1 to 1·2 mm.

Repairs to Scientific Instruments executed on the premises.

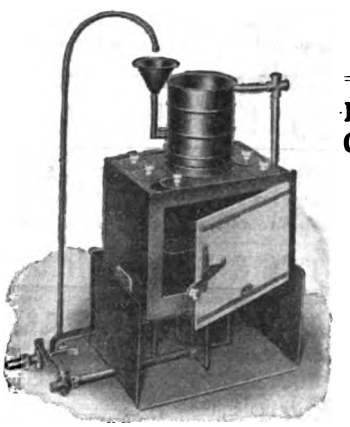
**KORISTKA MICROSCOPES**
OBJECTIVES AND EYEPIECES FROM STOCK.

**OGILVY & Co.**
18 BLOOMSBURY SQUARE, LONDON, W.C.
*Telephone: 1674 Gerrard.*

**AUTOCLAVES AND STERILIZERS**

Autoclaves supplied for all purposes in Iron, Steel, or Copper. Tinned or lead-coated, and pressures from ¼ to 100 atmospheres. With or without stirrers. Prices quoted according to capacity and pressure. Made also steam-jacketted, heating by paraffin oil, or oil bath.

We are now coating, with pure lead, electrolytically deposited, the Autoclaves where acid is used.



**PATENT [No. 6916] COMBINED OVENS AND STILL.**

This apparatus serves the purposes of drying oven, still, and evaporating bath. Made throughout of best hard rolled copper. Perfectly automatic in action, and economical in gas consumption. Where gas is not available they may be had for heating by steam pressure, petroleum oil, or spirit, and electricity.

*Fully Illustrated Catalogue Free.*

**BROWN & SON,**
ALEMBIC WORKS,
**9 Wedmore Street, Holloway, N.**

**Some Features in**

**WATSON'S "VERSALIC" 1/12 in. OIL IMMERSION OBJECTIVE.**

It has no equal for Laboratory purposes, and is particularly designed for hot climates.

**Mechanical Points.**
- The British Science Guild has recommended that Objectives should be sterilised before screwing home, to prevent growth of fungus, &c., in hot climates. This is done in the "Versalic" 1/12 in.
- The B.S. Guild also recommended that the mounting should be of a colour to make the Lens easily distinguishable. The "Versalic" 1/12 in. is finished black.
- In addition, the lenses are NOT set in their Cells with cement, which is apt to become unreliable, but all lenses are fixed with a metal bezel; they cannot therefore become displaced, the front lens cannot be "pushed in."

**Optical Points.**
- Working distance of exceptional length—the maximum that can be given with maintenance of immersion oil contact. Unusually flat field. Corrected for use on stained objects.
- Magnifying power is that of other 1/12 in. Lenses to which Laboratory workers are accustomed, viz. 1/8th in. It is a nominal 1/12 in. Definition is superb, and the Lens a pleasure to use.

**The Objective is British made.** It is designed for the Bacteriologist. It is especially recommended for hot climates. It will stand continuous rough working.

**PRICE £5. IMMEDIATE DELIVERY.**

WATSON'S MICROSCOPES are reliable and accurate. The demand exceeds the supply because their works are necessarily diverted to Optical Munitions. Inquiries are invited, and an approx mate date for deliv ry will always be given.

*Send for Catalogues* { *MICROSCOPES and ACCESSORIES (No. 2)* / *MICROSCOPES for METALLURGY (No. 2)* / *PHOTOMICROGRAPHIC APPARATUS* / *MICROSCOPIC OBJECTS (No. 3* } *Post free on request.*

# MACMILLAN & CO.'S NEW BOOKS.

## Political Frontiers and Boundary Making.

By Col. Sir THOMAS H. HOLDICH, K.C.M.G., K.C.I.E., C.B., D.Sc., Author of "The Gates of India." 8vo. 10*s.* net.

*THE FIELD.*—"The whole book is full of fascinating interest and present-day value."

**1916 ISSUE NOW READY.**

## The Statesman's Year-Book.

Statistical and Historical Annual of the States of the World for the Year 1916. Edited by J. SCOTT KELTIE, LL.D., assisted by M. EPSTEIN, M.A., Ph.D. With Maps. Crown 8vo. 10*s.* 6*d.* net.

VOLUME II. NOW READY.

## The Deposits of the Useful Minerals & Rocks; Their Origin, Form, and Content.

By Dr. F. BEYSCHLAG, Prof. J. H. L. VOGT, and Dr. P. KRUSCH. Translated by S. J. TRUSCOTT, Associate Royal School of Mines, London. Vol. II. LODES—METASOMATIC DEPOSITS—ORE-BEDS—GRAVEL DEPOSITS. With 176 Illustrations. 8vo. 20*s.* net. Previously published: Vol. I. Ore-Deposits in General—Magmatic Segregations—Contact Deposits—Tin Lodes—Quicksilver Lodes. With 291 Illustrations. 8vo. 18*s.* net.

*** These two volumes form the complete work on Ore-Deposits.

*ENGINEERING.*—"The literature quoted shows how thorough and exhaustive has been the research, and with what completeness the authors have achieved their task. . . . The authors have been very fortunate in finding a translator so well equipped for the task, at which he has worked with as much success as industry."

## Discovery; or, The Spirit and Service of Science.

By Professor R. A. GREGORY. With 8 Plates. Crown 8vo. 5*s.* net.

*ELECTRICAL ENGINEERING.*—"At a time when the sins of others are keeping our thoughts trained on the applications of human knowledge to the destruction of human life, it is a welcome relief to turn to this graceful volume, in which Prof. Gregory preaches to us, with no small literary ability, the beautiful gospel of Science for its own sake. Roaming over many fields of endeavour, he tells of the work of the great minds who have striven throughout the ages to add to our understanding and appreciation of our stupendous universe."

PART IV. JUST PUBLISHED. COMPLETE IN 1 VOL. (Pts. I.–IV.) NEARLY READY.

## A Class-Book of Chemistry.

By G. C. DONINGTON, M.A., late Senior Chemistry Master, City of London School, Author of "Practical Exercises in Chemistry." Illustrated. Crown 8vo. Part I. 1*s* 6*d*. Parts I. and II. 2*s*. 6*d*. Parts II and III. 2*s*. 6*d*. Parts I.–III. 3*s*. 6*d*. Part IV. METALS. 2*s*. Complete in 1 Vol. Pts. I.–IV. 5*s*.

*NATURE.*—"The earlier parts have rendered useful service to the teaching of elementary chemistry, and the present volume is up to the level of those previously issued."

## A Laboratory Manual of Foods and Cookery.

By EMMA B. MATTESON and ETHEL M. NEWLANDS. Crown 8vo. 6*s*. 6*d*. net.

## A Manual of Practical Physics.

By H. E. HADLEY, B.Sc., A.R.C.Sc., Principal of the School of Science, Kidderminster. Illustrated. Globe 8vo. 3*s*.

*NATURE.*—"Mr. Hadley is the author of a number of excellent works on physics, and the present small volume gives further proof of his ability as a clear exponent of physical principles. The book is suitable for the upper classes at schools where practical physics forms, as it should do, part of the science course."

## A Text-Book of Practical Physics.

By H. S. ALLEN, M.A., D.Sc., Senior Lecturer in Physics, University of London, King's College, and H. MOORE, A.R.C.Sc., B.Sc., Lecturer in Physics, University of London, King's College. Extra crown 8vo. 8*s*. 6*d*. net. Also PART I. PROPERTIES OF MATTER. 3*s*. net. PARTS II., III., and IV. SOUND, LIGHT, AND HEAT. 3*s*. net. PARTS V. and VI. MAGNETISM AND ELECTRICITY. 3*s*. net.

*NATURE.*—"The book as a whole is a valuable addition to the list of text-books on practical physics, and the authors show an intimate acquaintance with the difficulties of both students and teachers which should make it very acceptable to both."

PART II. NOW READY.

## Practical Mathematics for Technical Students.

Part II. By T. S. USHERWOOD, B.Sc., Wh.Ex., A.M.I.Mech.E., and C. J. A. TRIMBLE, B.A. Crown 8vo. 7*s*. 6*d*.

*** Previously published: Part I. 3*s*. 6*d*.

LONDON, E.C.

Applications are invited for the following full-time vacant appointments in the Civil and Mechanical Engineering Department:—

(1) DEMONSTRATOR and ASSISTANT LECTURER. Salary £140 per annum.

(2) LABORATORY MECHANIC and JUNIOR DEMONSTRATOR, with good practical knowledge of the working of Heat Engines. Salary £120 per annum.

Particulars and forms of application for either of the above can be obtained on application to R. MULLINEUX WALMSLEY, D.Sc., Principal.

## BIRKBECK COLLEGE,

BREAMS BUILDINGS, CHANCERY LANE, E.C.

COURSES OF STUDY (Day and Evening) for Degrees of the UNIVERSITY OF LONDON in the

## FACULTIES OF SCIENCE & ARTS

(PASS AND HONOURS)

Under RECOGNISED TEACHERS of the University.

**SCIENCE.—Chemistry, Physics, Mathematics (Pure and Applied), Botany, Zoology, Geology.**

**ARTS.—Latin, Greek, English, French, German, Italian, History, Geography, Logic, Economics, Mathematics (Pure and Applied).**

***Evening Courses for the Degrees in Economics and Laws.***

POST-GRADUATE AND RESEARCH WORK.

SESSIONAL FEES { *Day:* Science, £17 10s.; Arts, £10 10s. *Evening:* Science, Arts, or Economics, £5 5s.

*Prospectus post free, Calendar 3d. (by post 5d.), from the Secretary.*

## SOUTH-WESTERN POLYTECHNIC INSTITUTE, CHELSEA.

Day and Evening Courses in the Faculty of Science and Engineering.

Technical Chemical Courses.

Pharmacy and Dispensing Courses.

Particulars may be obtained on application to the Secretary (Room 44). SIDNEY SKINNER, M.A., Principal.

Telephone: Western 899.

## LURGAN URBAN DISTRICT.

WANTED, PRINCIPAL AND SECRETARY FOR TECHNICAL SCHOOL.

The Lurgan Technical Instruction Committee require the services of a PRINCIPAL and SECRETARY (to devote his whole time to the work of the School), possessing qualifications in Technology recognised by the Department of Agriculture and Technical Instruction, and having had experience of the working of Technical Schools. Salary £200 per annum.

Applications, stating age, &c., will be received by the undersigned not later than 12 o'clock noon on Friday, November 24, 1916.

Canvassing by or on behalf of candidates will be deemed a disqualification.

J. W. POLLOCK,
Acting Secretary.

Technical School, Lurgan,
October 24, 1916.

## DERBY EDUCATION COMMITTEE.

TECHNICAL COLLEGE.

The Governors invite applications from qualified candidates for the post of LECTURER and DEMONSTRATOR in CHEMISTRY. Salary £300 per annum.

Forms of application may be obtained from the PRINCIPAL, Technical College, Derby, to whom they should be returned not later than Monday, November 13, 1916.

WILLIAM COOPER, Secretary.

October 23, 1916.

## FORM & FUNCTION

**A Contribution to the History of Animal Morphology.**

By E. S. RUSSELL, M.A., B.Sc., F.Z.S.

**394 Pages. Demy 8vo. 10s. 6d. net.**

This book deals with the principles of comparative anatomy, under the form of an historical account of the development of the science from Aristotle to W. Roux. Three main currents of morphological thought are distinguished—the functional or synthetic, the formal or transcendental, and the materialistic or disintegrative.

## THE SCHOOL OF PYTHAGORAS.

*Le Scuole Ionica, Pythagorica ed Eleata (I Prearistotelici, I.)* By Dr. Aldo Mieli. Pp. xvi + 503. (Firenze: Libreria della Voce, 1916.) Price lire 12.

THAT the study of history maketh a man wise was the saying of a great Elizabethan, but it was one of the great Victorians who preferred a copy of the *Times* to "all the writings of Thucydides"; the great days of Elizabeth would not seem so spacious had one or two such sayings as the last come down to us from them! An historic sense was somewhat far to seek in the Victorian age. The nineteenth century had all but forgotten its own past. Lyell and Darwin, Schwann and Virchow, Lister, Faraday and Joule had a way of making their immediate predecessors look old-fashioned, as the post-chaise looked when the railway came. In short, so great a revolution had taken place in things mental as well as in things practical that it seemed (so Judge Stallo said) as though Bacon's demand had at last been thoroughly complied with, *ut opus mentis universum de integro resumatur.*

I never heard a lesson in my school- or college-days on the historical aspect of any science, though some few of our teachers were by no means unacquainted with history. One was on intimate terms with Ray and Willughby, and all the older English naturalists; another got no small part of his large wisdom from Boerhaave and Haller, and even Ambroise Paré. There was yet another who led his pupils (his better pupils) to Newton, while his neighbours were perfectly satisfied with Frost. When one thinks how deep was the reading, how wide the learning, of men like Sharpey and Rolleston, Alfred Newton and Michael Foster, it is all the more striking that even by them the historical method was very seldom employed and the love of history very little instilled. The fact is, we were all dazzled and obsessed, young and old, by "the great press of novelty at hand." Linnæus and Cuvier, even Johannes Müller himself, had read their Aristotle to learn of him, just as they read their Swammerdam and their Réaumur. But we had come to think of the old books as so much bric-à-brac, as material for a hobby but of no more use in the world. The tide has turned since those days, one scarce knows how or why; and a world that is as busy as ever finds more time for the study of history than it did. The long series of Ostwald's "Wissenschaftliche Klassiker" is proof of a widespread desire to consult the sources of knowledge; and Mach's "Science of Mechanics" is perhaps the best but not the only example of the historic method, rigorously and critically applied to the teaching of a science.

Dr. Aldo Mieli, the writer of the book before us, is already known by a number of historical articles in *Scientia*, that admirable journal of our Italian allies; we may welcome him accordingly as a member of the little company of historical students, of which Prof. Gino Loria is the distinguished head. He all but takes our breath away, in his very preface, by the vastness of his conceptions and his projects, while he relates with ingenuous sincerity the recent history of his own mental development. He had a thirst for universal knowledge in his schooldays, and essayed to comprehend, "con l'aiuto di poche premisse, tutti i fenomeni fisici e sociali, artistici e filosofici." He presently sought in mathematics, but sought in vain, for the inner meaning, "la spiegazione," of things. When he failed there, he betook himself in haste to chemistry; "a corpo perduto mi gettai allora (1902) nello studio della chimica!" He was baffled again; he had striven as the old alchemists strove, and his longings, like theirs, were unfulfilled. At last, under the influence of Mach and Ostwald, he turned to history and to philosophy; renouncing the search after a "rational and experimental explanation of the world," he resolved to study the creations of the spirit, and to trace in particular the development of scientific thought.

While charmed by these naïve confessions of the young Italian scholar, the reader is startled to discover that the present bulky book is but the first part of a universal history, on a scale vaster than Gibbon's or Hallam's, of the whole circle of the sciences. It is to be divided into some seven portions, dealing with the great ancient pre-Hellenic empires, next with Hellenic, Arabic, and Far-Eastern science; again, with the Middle Ages and with the Renaissance to Galileo's day; and lastly, with the seventeenth and eighteenth centuries. The story of Hellenic learning will be divided into four parts, of which one must end where Aristotle's work begins; and this pre-Aristotelian treatise will be in three volumes, of which one is the book before us, and the other two will deal in due time with the Atomists and with Plato and the Sophists.

The reader may be a trifle prejudiced, he might be dismayed or even dumfounded, by so vast an ambition. But the fact is that the book is marvellously well done—so far as the present writer is capable of judging. Big as it is, it is compact and full; it leads us smoothly and easily, with but brief and impartial discussion, through the subjects on which we expect and desire to be informed. We hear the legendary history of Pythagoras and his confraternity; we are introduced to the philosophy, the science, and the mystical mathematics of the school. We learn in successive chapters, for instance, of the mystical theory of number; of figurate and other curious numbers, and of the *proportio divina*; of the great Pythagorean theorem, and of the gnomon; of the concepts of application and of excess and defect; of the principles of acoustics and of the musical scale, and of the astronomic and other theories of Archytas and Philolaus and the rest. The subjects are those with which any book or encyclopædia article on Pythagoras is bound to deal, and

Digitized by Google

there is little here but what we can get from others. But here it is, well and clearly ordered and expressed, and abundantly furnished with all sorts of guide-posts for those in quest of still more information or discussion.

The bibliographical lists are astonishingly good, without pretending to "completeness." The one, for instance, which is appended to the first section of our volume is of a general kind, and covers some seventy pages; it pilots the student to the texts of Diels, Mullach, and others; to works on the history of philosophy, Greek and other, from the days of Ritter and Preller to Zeller and Burnet and Diels; and ends with a capital account of the historians of mathematical, astronomical, and physical science, from Bailly, Montucla, and Delambre, to Allman and Zeuthen, and Moritz Cantor and Paul Tannery and Sir Thomas Heath. There may be mistakes, for aught I know, in this learned and compendious book, but I have neither found them nor sought for them. It was one of Pythagoras's sayings (or Dr. Johnson tells us so) that a friend should not be chidden for little faults.

Pythagoras is one of the great figures of the world, and many and many a scholar has had a predilection for him: Sir Thomas Browne loved him; Plato was steeped in his doctrine; and whole books of Euclid are ascribed to his teaching. Those who knew least of him could always quote him, as Shakespeare did, and Dr. Johnson, and as Goldsmith quoted Ocellus Lucanus. But the more we read about Pythagoras the less we know of him for sure and certain; and it is just herein that his peculiar fascination lies. For he is one of those shadowy figures who stand on the borderland between history and fable, between fairyland and reality: like King Arthur and Thomas of Ercildoune and King Solomon and Caliph Haroun al Raschid. We know that one of his legs was of gold, that Apollo was his father, that heavenly messengers flew down to him on golden arrows, and that his face shone like the faces of the Shining Ones. In more sober statement he seems to represent the continuity, unbroken but dwindled to a thread (a thin but indispensable thread), between one civilisation and another, between the beginning of Greek thought and the decline of learning in a remote but erudite antiquity. To the student trying to prefigure so strange and so elusive a personality there is a choice of ways. If he keep to sober and critical consideration of the meagre facts at hand, he will probably arrive at the conclusion that there is no evidence for Pythagoras having learned anything worth speaking of upon his travels or having inherited any load of learning from pre-Hellenic science and philosophy. So it is commonly held by many men of the soundest classical learning that no foreign influence can be traced in the school of Pythagoras, and that his "philosophy and institutions contain nothing but what might easily have been developed by a Greek mind exposed to the ordinary influences of the age." Dr. Allman held, with all due caution, that we must be "struck with the Egyptian character of the geometrical work attributed to Pythagoras"; but Prof. Burnet asserts that all the mathematics of the Egyptians consisted of a few rules of thumb by which to measure the area of a field or the height of a pyramid, and denies that Egypt had anything to teach Pythagoras that was worth the learning or the borrowing.

On the other hand, there is ample room for others, of a more imaginative disposition, to grope among the ruins and the misty darkness of pre-Hellenic civilisation, to put two and two together wheresoever they can, and to apply themselves (for a while at least) to the ingenious art of fanciful reconstruction. Dr. Naber's curious book, "Das Theorem des Pythagoras," is of the latter kind. The ground on which he leads us is sometimes dangerous, as when he depends on Piazzi Smyth for his facts as well as his theories of the pyramid; but for all that he weaves a fascinating and instructive story. He brings together a prodigious mass of curious lore about the triangle and the pentagon, and the Sacred Letter, and the Symbol of Health, and Abracadabra, and the sacred lotus and mallow-flower; he touches on a hundred things which the early students of the triangle must (in all likelihood) have observed and discovered by the way; and he suggests with no less ingenuity the lines of tradition along which such knowledge ran, from far-away antiquity even to the artists and cathedral-builders of the Middle Ages.

If we be inclined to see in Pythagorean mathematics not the discoveries of a single lifetime but fragments of the learning of a preceding age, so also in his philosophy may we be inclined to recognise parts of a great edifice the scattered stones of which confront us in unexpected places, built into the fabric of old but less ancient walls. We have often heard that there is a curious link or bond between the Cabbalists and the Pythagoreans; and now again, in a recent *Hibbert Journal*, an article by the Chief Rabbi on "Jewish Mysticism" suggests, though it does not assert, this view. The "opinion of Pythagoras" regarding metempsychosis, wholly absent from Bible and from Talmud, is fundamental to the teaching of the Cabbala. In Cabbalistic as in Pythagorean philosophy the ten numerals, or Sefiroth, contain the possibilities of all things, and, with the help of language, represent the Spirit of God; the mystical number Ten is the material universe, God's kingdom made visible; wisdom and understanding, mercy and justice and harmony are among the concepts which other numbers represent or embody; and the mystical One is the mystery of mysteries, which in the beginning filled all space and was all space. Then "En Sof contracted Himself in order to leave an empty space for creatures"; just as, according to Pythagoras, *ἐπεισάγεσθαι δ' ἐκ τοῦ ἀπείρου χρόνον τε καὶ πνόην καὶ τὸ κενόν*. The Pythagorean, or Platonic, or Jewish concept of Number is a hard saying to the unpoetic, non-mystical modern and Western world; and many a way is found to show that Plato and Pythagoras meant something prosy and commonplace after all. But to some it is still as plain as ever that Number is the clue to the greatest of

Digitized by Google

earthly mysteries, and that what we call beauty, whether of sound or form, is but its resultant and expression. It was in the very spirit of Pythagorean mysticism and wisdom that that great naturalist, Henri Fabre, wrote his great ode to number; as in a kindred spirit the old carpenter in Verhaeren's poem:

"Fait des cercles et des carrés,
Tenacement pour démontrer
Comment l'âme doit concevoir
Les lois indubitables et fécondes
Qui sont la règle et la clarté du monde."

We must never forget that the secrets of the mystic, whether Gnostic, Cabbalist or Pythagorean, lie very deep indeed, and that a twin alternative between esoteric and exoteric statement, or between literal and allegoric interpretation, by no means exhausts the various meanings which the mystical philosopher can wrap up in his words. In the end, as we come slowly to a better, though still a clouded, understanding of what lies within and behind the Golden Verses and all the rest of the husk of Pythagorean tradition, we feel the truth and force of William James's saying (aptly quoted in the article to which I have just referred), that the "mystical classics have neither birthday nor native land; their speech antedates language, and they do not grow old."

D'ARCY W. THOMPSON.

## PHYSIOLOGICAL CHEMISTRY.

*Physiological Chemistry: A Text-book and Manual for Students.* By Prof. A. P. Mathews. Pp. vii + 1040. (London: Baillière, Tindall and Cox, 1916.) Price 21*s.* net.

PROF. MATHEWS is well known as a worker in the field of physiological chemistry, more especially on its physical side. His present volume is one of an ambitious character, and has the merit of being distinctly original. The chapters on the chemistry of the fats, carbohydrates, and proteins are fuller than is usual in such books, and the subject-matter is not only clearly explained, but is fully up to date. Much of it is pure chemistry, but it will not be less valuable for that reason to the biologist. The section on physical chemistry is also treated at considerable length, as might have been anticipated by those who know the author's bent. The whole subject is confessedly treated unequally, for, as the preface puts it: "Of so large a subject one can be personally familiar with but a small part." The portions that strike one as susceptible of more expansion are those dealing with muscle and the ductless glands; for the latter group of organs Prof. Mathews coins yet another name: he dubs them the Cryptorhetic Organs—*i.e.* organs with a hidden flow. One small feature of the book—viz. the explanation and derivation of technical terms—might well be imitated in more elementary manuals than the present. While on the question of words, one may add that the nomenclature adopted for the fats and fat-like substances is one not likely to commend itself to all physiologists.

Each chapter is followed by a short selected list of papers bearing on the subject dealt with in that chapter. There is no attempt at a complete bibliography, but the selections appear to have been judiciously made, though in the present state of the political atmosphere German writers figure rather too largely for English taste. The papers mentioned for reading and study are mostly recent ones, because they approach the subject from the modern point of view, and in them the older literature is cited. The choice does not imply that the author does not value the work of the early pioneers; indeed, he presents evidence that he takes the opposite point of view, and the full consideration which he gives to their work forms one of the most interesting features of his book. He, for instance, gives a very extensive account of the researches of Lavoisier, whom he perhaps rightly regards as the founder of bio-chemistry, of Beaumont, of Claude Bernard, and many others.

Prof. Mathews, who is here the exponent of a vast but nevertheless comparatively young branch of science which every day is becoming more and more exact, is not devoid of a sense of imagination, the most valuable asset of both a teacher and a researcher. His excursions into the regions of speculation will be read with keen interest, even although, like so many hypotheses in the past, they may ultimately be forgotten. Such theories as those which he advances in his comparison of the animal body to a magnet, or in his conception of the "conservation of psychism," or in his attempts to explain memory on a chemical basis, will certainly stimulate thought and future investigation. To quote once more from the preface: "It is hoped that this book will raise in the mind of those who read it more questions than it answers."

The last 160 pages of the book are devoted to a description of the laboratory work in physiological chemistry as carried out in the University of Chicago, and practical teachers will obtain many useful wrinkles by studying these. W. D. H.

## OUR BOOKSHELF.

*Cambridge Geological Series. Agricultural Geology.* By R. H. Rastall. Pp. ix + 331. (Cambridge: At the University Press, 1916.) Price 10*s.* 6*d.* net.

MR. RASTALL'S well-written and excellently printed book is a treatise on geology for agricultural students rather than on agricultural geology. To say this is no disparagement, since it is obviously intended for the stage in an agricultural curriculum when natural history subjects are predominant, and not for the later years when preliminary scientific conceptions are applied to the study of the soil. A knowledge of chemistry and elementary mineralogy is presupposed, but unnecessary technical terms are carefully excluded. The final chapter, on "The Geological History of the Domestic Animals," will appeal especially to those whose work is on the farm. The history of life on the globe is, indeed, far more appreciated by agricultural scholars than

Digitized by Google

our text-books would commonly lead us to suppose. The details of British strata, such as the Ashgill Shale and the inevitable Oldhaven Beds, are still reverenced by examining boards, but are far less important than a philosophic outlook on the great romance leading up to man, the tiller of the soil. Mr. Rastall, however, makes good use of his opportunity, and gives us attractive descriptions of the types of country met with on various strata throughout England.

The chapter on soils, occupying twenty-eight pages, is a good example of the author's method. It contains a large amount of information without any appearance of compression; the details given fit into a continuous and pleasing essay. We unfortunately get no conception of the variations in the "fine earth" of soils, on which their fundamental characters depend, such matters being left (p. 144) to more purely agricultural teaching. Phosphatic deposits (p. 100), however, come within the geologist's province, and here we think that more analyses might have been inserted and a description given of materials, such as the beds of Florida and Gafsa, which are being worked commercially at the present day.

G. A. J. C.

*British Rainfall*, 1915. By Dr. H. R. Mill and Carle Salter. The fifty-fifth annual volume. Pp. 288. (London: Edward Stanford, Ltd., 1916.) Price 10*s*.

DR. MILL has been able, with the assistance of Mr. Carle Salter and Mr. R. C. Mossman, to prepare his annual account of British rainfall with almost the usual pre-war promptitude. The special feature of the volume lies in an account of the method of construction of a rainfall map, which is illustrated by a map of the Forth Valley above Queensferry, including an area of almost 1000 square miles. The fundamental rainfall facts are closely related to the elevation of the land and to the prevailing winds, and this relationship makes it possible to draw isohyets across districts where rain gauges are infrequent, with the result that as the years go by these rainfall lines approximate more and more closely to the final form which they will eventually take.

In May–June, 1915, practically the whole of Great Britain experienced absolute drought for twenty days. This was an unusual occurrence for Scotland. On the other hand, the west coast of Ireland and the north-west corner of Scotland had a rain spell which lasted from sixty to more than 100 "rain-days" consecutively. Remarkable rain splashes occurred at Abergavenny on July 4, when 2·2 in. fell in thirty minutes, and at

### The Germans and Scientific Discovery.

A GOOD deal is being written on the terms of peace and on our attitude towards the Germans after the war in the spheres of pure science, applied science, and industry generally. While these and similar topics are in the melting-pot of controversy, this might be the suitable time to bring up the subject of the attitude of Germans towards the history of science in general, and towards the part played in scientific discoveries by English-speaking people in particular.

Those familiar with German utterances during the last twenty years or so know well that German men of science, in giving the historical *résumé* of a subject, scarcely ever mention the names of British workers in that field. There is virtually a conspiracy of silence, especially as regards recent and contemporary workers. One would think, to read some German accounts of a subject, that it had been begun, continued, and ended in Germany.

To make our enemies realise to what an extent they are indebted to British thinkers would be one most excellent result of this dreadful war. Of course they know it; but they systematically conceal it; it should be a valuable part of their chastisement to be made now to confess it. They have concealed the successful part played in scientific discovery by English-speaking people as systematically as they have concealed the successes of the Allies in the present international conflict. They should be cast down from their self-assumed pride of place in the matter of scientific discovery, and made to confess who were the real pioneers in the painful fields of scientific work. It is well known that many truly epoch-making discoveries, things of the very first magnitude, were made by Britons, and that afterwards the Germans came in and adopted and utilised these discoveries in the interests, for the most part, of the expansion of their trade.

As one of the conditions of their being granted peace by those who shall conquer them on their own selected arena of brute force backed by perverted machinery and prostituted chemistry, they should be made publicly to acknowledge the enormous benefits to science made initially, not by themselves, but by those whom they forced to become their enemies, the Italians, the British, and the French.

It would be a salutary humbling of their scientific pride to be made to confess that it was the Englishman, Newton, who discovered the law of universal gravitation; the Englishman, William Harvey, who discovered the circulation of the blood; the Englishman, Priestley, who first isolated oxygen; the Scotsman, Joseph Black, who discovered the chemical relations of carbon dioxide; and the Scotsman, Rutherford, who discovered nitrogen gas. They must be made to know that the Englishman, Stephen Hales,

Digitized by Google

inventions of English-speaking people. The bicycle and the aeroplane were devised on the soil of Britain.

It was Faraday, they should be made to confess, who laid the basis of electromagnetics, and therefore the foundations of that amazing industrial application of electricity as a mode of motion. It was Davy who showed the elemental character of the alkaline metals —a discovery of the greatest moment. They must be made to realise that Boyle, Cavendish, Watt, Stephenson, Leslie, Hutton, and Lyell, as well as John Hunter, Jenner, Simpson, and Lister, were Britons who made discoveries of the first importance. They must be forced to confess the supreme character of the work of Napier, the Herschels, Adams, Clerk-Maxwell, and Kelvin. We, on our part, always acknowledge the indebtedness of science to such Germans as Mayer, Helmholtz, and Ehrlich; whereas our enemies systematically conceal their immense indebtedness for the enunciation of first principles to men of the English-speaking race.

In regard to the splendid contributions to science of every kind made by the Italians and the French, the representatives of those nations must draw up their own lists, and they will not be short ones. The names they must contain suggest cardinal discoveries in every field of natural knowledge. It would be tedious to revert to the Italian Renaissance, because the names of the men of that epoch have become well known to anyone who knows anything at all of the story of the progress of science.

Eustachius, Malpighius, Borelli, Spallanzani, Galvani, Volta, and Avogadro in Italy; Lavoisier, Laplace, Lagrange, Montgolfier, Cuvier, Lamarck, Claude Bernard, Chevreul, and Pasteur in France, are names writ large in letters of gold across the azure of the firmament of European science. Not one of the following is German: Vesalius, Van't Hoff, Arrhenius, Helmont, Boerhaave, Mendeléeff, the Curies, Metchnikoff, and Pavlov.

Are the Germans grateful to us for what we have done in science? Do they realise, when they use railroads and steamers, dynamos and telephones, that they are all of British origination? They realise nothing of the kind. Not only are they not grateful for the benefits conferred on them by British science, but they have entered into a conspiracy of silence with regard to them.

Let us never forget that it was a German professor of physics who deliberately declared that German aircraft must destroy the tombs of Newton and of Faraday. He also included the tomb of Shakespeare, which was highly inconsistent with the widespread academic delusion that our and the world's greatest poet was a German.

D. FRASER HARRIS.

Halifax, Nova Scotia, September 30.

## The Spectrum of Hydrogen.

THE writer has examined the four-line spectrum of hydrogen as produced in Geissler tubes with a 1 mm. capillary by alternating current of 15 milliamperes without inductance or capacity. The light was analysed by a glass prism monochromator, and the intensities measured by a photo-electric [illegible] spectrum masks the effect when pure dry hydrogen is used.

The results lead to the conclusions that the four-line spectrum is due to the recombination of a $+H$ ion with an electron; that the method of ionisation of the H atom has no effect on the distribution of intensities, but that the mean free path of the luminous atom and the nature of the atoms with which it collides give a sufficient explanation of the intensity changes observed.

According to Bohr's theory, the mean free path of a luminous hydrogen atom should be shorter as the emitted wave-length decreases. The distance travelled by the atom while luminous may be called the length of the luminous streak, and at high pressures this exceeds the mean free path of the luminous atom for all wave-lengths, so that a change in pressure affects all lines in the same proportion. As the pressure is lowered, however, the mean free path will eventually exceed the length of the luminous streak for $H_\alpha$, while remaining less for $H_\beta$, and so the ratio $H_\beta \div H_\alpha$ may be expected to increase, as is actually observed. At still lower pressures the intensity ratios should approach a constant value when all the mean free paths are greater than the corresponding luminous streaks.

Observation of such ratios will give the relative energies in different wave-lengths emitted by the hydrogen atom when undisturbed by collisions, and experiments of this kind are in progress.

A full account of this work will be published shortly.

R. T. BEATTY.

Queen's University, Belfast, October 18.

## Origin of the Word "Blizzard."

THERE have been a number of communications on the earliest use of the word "blizzard," but thus far there has been no suggestion as to its origin. At first sight perhaps it might seem unlikely that the name of some objectionable person was adopted to describe the extremely disagreeable features of the north-westerly snowstorm of the States. We have, however, "boycott" and other words added to our vocabulary with just as much justification as the old settlers in the West would have had for introducing "blizzard."

In Amersham churchyard there is a tomb (now collapsing into the grave) of the Blizard family (Otto Bajer), and to this day, at the neighbouring village of Chalfont St. Giles, there resides a Blizard family. We are here in the heart of the Penn country, the Home of America. It seems highly probable that one or more members of the Blizard family of Buckinghamshire emigrated with the earliest settlers, and it needs no great stretch of the imagination to realise how the name could have been adopted in the slightly altered form "blizzard." I offer the suggestion to the world-wide readers of NATURE.

HY. HARRIES.

of munitions before their eyes. It should be instructive to see what conclusions have been reached by a people with a genius for reducing everything to machinery, from the production of motor-cars to education.

The first step, in a democracy, was to bring home to every citizen the importance of the problem. Some of us may have smiled at the picture of the President of the United States, clad in a straw hat, a navy-blue jacket, and cream-coloured duck trousers, marching at the head of a great "Preparedness" procession, and waving a flag with the best of them. But Mr. Wilson knew what he was about. The Americans are incomparable advertisers. No other device could have so instantly focussed the attention of the whole mass of heterogeneous populations between the two coasts. This having been effected, the plan evolved by the Naval Consulting Board's Committee on "Preparedness" was set out in a series of articles written by leading Government officials and business experts, and introduced by an open letter from the President himself. Which of the great political journals was entrusted with this weighty national publication? The shocking truth cannot be concealed that it was not to the editor of anything analogous to our *Times* that the President wrote his letter with full confidence that it would reach the people. It was to the *Scientific American*—as it might be our own *Engineering*—and there the articles appeared during the late spring of the present year.

They start with what seems to them an axiom, though it is still so difficult for many of our fire-eaters to realise it: "The one great lesson of the European conflict is that defence is not obtained to-day by fighting *men* alone, but by fighting *industries*. Behind every man in the firing line in Europe, from three to five persons are employed to supply him with food, ammunition, and other needs." Their experience of the first year of the war convinced them that the people will never reach the right point of view till they realise "what a mess we have made of our attempts to supply munitions to the Allies." So an article is devoted to the initial difficulties. A large firm in the West is instanced, which cheerfully took on a contract for 250,000 3-in. high-explosive shells.

It seemed a simple and profitable job. But the firm soon realised that by turning their plant—a first-class machine shop—on to it they might hope to accomplish it in eight months, and then it would only be one day's supply for *one* of the Allies. But so many difficulties intervened that after eighteen months they had only 100,000 shells accepted, which still had to be fitted for the Allies, would require in gauges and measuring tools alone an investment of from seventeen to twenty million dollars. Many of the best-known firms in the U.S. had been at work a year on the provision of this preliminary outfit without turning out sufficient finished product to be worth inspection. They have "made up their minds that if they are ever to be called on for the service of the nation they have to learn a great deal more about this business of making munitions, or in the event of war they would prove to be liabilities to the nation and not assets."

The plan worked out by the Naval Consulting Board is then expounded. It involves three steps:—

The first step consists in the taking of a complete census of the producing resources of the country, to be tabulated on a card index. This is to include an inventory of industrial manufacturing establishments which, it is thought, will cover eighty thousand firms.

The index will show the ground area, floor space, number of stories, housing accommodation, and possibility of increase in emergency; sources of heat, light, water, power; tool equipment idle in slack season; limits of precision in machine work, principal materials used and where purchased, and principal products manufactured; number of men, skilled and unskilled, number of toolmakers, of women, and of men who could be replaced by women; percentage of employees who are not American citizens; means of transport, trucking distance, and quality of street service to shipping point, trucks owned and hired, and shipping facilities by water.

The census is to cover the resources of the country in minerals and materials, with special stress on petroleum supplies and the utilisation of water-powers. To prepare it President Wilson invoked the aid of the five great engineering societies—civil, mechanical, mining, electrical, and chemical. In every State a member of each of the five societies has given his services gratuitously to form a board of five directors for the State, and under the supervision of these boards the 30,000 members of the societies have been at work. The Chambers of Commerce have given their aid, private firms have provided offices and furniture free of cost, and the newspapers have given advertisements and articles to boom the movement. It was expected that the bulk of the work would be completed by the end of May, 1916.

The second stage of the plan will consist in placing small educational orders for munitions with large numbers of selected firms annually in time of peace.

Digitized by Google

partment will become familiar with Governmental inspection; the engineering department with Government blue-prints and specifications; the firm with Governmental methods of business; and the shipping department will know how to crate and ship the finished article.

The terms on which these contracts are to be made are significant. They are to be on a basis of cost plus a reasonable profit, or at a fixed dividend. There are to be no excess profits for anybody arising out of the national need, but the stockholders are to have a living wage, "since it is economically undesirable that the stockholders cease to have any dividend from their investment"! In this way will be prevented any suggestion of a profit-interest in war, of a munition lobby, of a section of the community having an interest in forcing the nation into war. If there is a war every person in the nation must accept his share of the national sacrifice and turn in and work in whatever place his ability can be best applied.

The third and final step in the programme is the enrolment of skilled labour in an "Industrial Reserve" in time of peace. Skilled mechanics in all lines of production must be kept from enrolment in the Army. Rather must bankers, clerks, shopkeepers, and professional men be sent. The skilled workers must be badged, and the only restriction imposed on them by the badge will be prevention of enlistment. Enrolment in the Industrial Reserve will be considered to carry with it honours equal to enrolment in the fighting forces.

It is claimed that this plan is a most democratic and American way of doing the job. It is cheap; it lays the ghost of a munitions trust, with its dangerous interest in provoking war; it safeguards labour from exploitation for excess profits; it educates the manufacturers; and it is not only an insurance against war, but it has great advantages in peace.

Direct organisation for peaceful competition is dealt with in another series of articles. The survey of national resources and their conservation includes significantly "our 22,000,000 children." These must be trained, not only in the schools, but in the vital years between fourteen and eighteen, the waste of which has recently been pointed out by Mr. Galsworthy in the Press and Lord Haldane in the House of Lords. The methods of intensive industrial efficiency which were coming into notice before the war must be continued and developed.

Other articles deal with the disposal of the finished products—the careful preparation of the ground in foreign markets by personal inquiries; by correspondence with consular agencies, chambers of commerce, and universities; by improved methods of packing and dispatch; and by cultivating the "human side of salesmanship." Some of the devices described under this last head would not commend themselves to British ideas, and are not perhaps very seriously urged. There is a thoroughgoing materialism in some of the utterances quoted which we could not accept. "Real immorality," says Prof. Carver, of the Economics Department of Harvard University, in a paper on the Conservation of Human Energy, "is nothing in the world except waste or dissipation of human energy. Real morality is nothing in the world except the economy and utilisation of human energy. The reason why it is better to tell the truth than to lie is because a community in which truth prevails will waste less energy than a community where lying prevails. . . . Honesty is one of the greatest labour-saving inventions ever devised. This may be said of any other form of morality which is genuine and not merely conventional."

There are things in our British life which we should not sell for all the markets in the world. But the treasuring of these ideals is not inconsistent with sane preparation to meet the tremendous competition we shall have to encounter in the material sphere at the conclusion of the war. What this preparation should be, in the opinion of President Wilson, is indicated in the letter addressed by him to the editor of the *Scientific American*, directing attention to the articles which have since appeared in that journal. We think it worth quoting in full:—

> It will be a signal service to our country to arouse it to a knowledge of the great possibilities that are open to it in the markets of the world. The door of opportunity swings wide before us. Through it we may, if we will, enter into rich fields of endeavour and success. In order to do this we must show an effectiveness in industrial practice which measures up to our best standards. We must avail ourselves of all that *science* can tell us in aid of industry, and must use all that *education* can contribute to train the artisan in the principles and practice of his work. Our industries must be self-reliant and courageous, because based upon certain knowledge of their task, and because supported by the efforts of citizens in the mills. If scientific research and the educated worker go hand in hand with *broad vision in finance* and with that keen *self-criticism* which is the manufacturer's first duty to himself, the fields will be few indeed in which American commerce may not hold, if it chooses, a primary place.

The significant thing about this letter is that there is in it no allusion to Protection. The President is for open operations by an industry relying on its own efficiency, not for trench warfare behind tariffs. Science, education, broad vision in finance, self-criticism—that is the programme. A nation which has imagination, courage, and honesty enough to depend on these can look forward without fear to whatever the future may have in store for it. J. C.

## *RHODODENDRONS AND LIME.*

IN a note in NATURE of February 17, 1916 (vol. xcvi., p. 684), reference was made to Mr. Forrest's discovery of rhododendrons growing on limestone rocks in N.W. Yunnan. In this connection Lady Wheeler-Cuffe, writing from Maymyo, Upper Burma, informs the Editor that she found "a beautiful blush-white rhododendron growing actually wedged into a bare limestone crag on the very summit of Sindaung (6022 ft.), in the southern Shan States, a few years ago." Mr.

Digitized by Google

Forrest also states definitely that he found rhododendrons with their roots actually spreading in the crevices of the limestone rock.

From the evidence of Mr. Forrest and Lady Wheeler-Cuffe it would appear that these particular rhododendrons must come in contact with a large quantity of lime, but, unfortunately, we have no definite information as to the particular character of the limestone rocks on which they have been found.

In the European Alps the two endemic species of rhododendron, *R. ferrugineum* and *R. hirsutum*, are recognised as being chalk-avoiding and chalk-loving respectively. *R. ferrugineum* is found in damp, deep-layered soil rich in humus, and it will only grow in a limestone region when there is an overlying layer of humus. *R. hirsutum*, on the other hand, is a limestone rock plant, found in dry, open situations, and when the two species are found in the same locality, *R. hirsutum* grows only on the rocks, while *R. ferrugineum* occurs in the pockets of humus. The hybrids which have been raised in gardens with *R. hirsutum* as one of the parents are also lime-loving, like that species.

Several of the new Chinese rhododendrons which were collected on limestone are now being experimentally cultivated in this country on various lime-containing soils. Some of the species (see Grove in *Gardeners' Chronicle*, January 29, 1916, p. 65) appear to thrive under these conditions very well, while to others the lime has proved fatal, but the experiments have not been in progress for a sufficiently long time for a definite verdict as to the behaviour of these limestone rhododendrons under cultivation to be given.

The abhorrence of lime by the humus-loving rhododendrons appears to be intimately connected with the mycorrhiza, the symbiotic fungus which lives in association with the roots of the rhododendron and heath family (Ericaceæ), and performs the functions of the root-hairs in absorbing water from the soil; and it may be that the mycorrhizal fungi associated with the humus-loving forms of rhododendron are physiologically, if not specifically, distinct from those of the lime-loving species.

It has recently been shown by Rayner, Jones, and Tayleur (*New Phytologist*, vol. x., 1911, pp. 227–240) that the common ling, *Calluna vulgaris*, though it is sometimes found on chalk downs, is really growing in pockets of loamy soil rich in mineral constituents but poor in lime. It is also worthy of note that in the "limestone pavement" district of Westmorland ling grows vigorously in the very thin layers of earth which lie directly on the limestone rock. An analysis of the surface soil, however, reveals an almost complete absence of lime, and so lime-free is this layer that it is actually necessary to add lime thereto in the course of ordinary agricultural operations.

Cultures made by C. A. Weber and Graebner (see Graebner, "Lehrbuch der Allgemeinen Pflanzenphysiographie," 1910, p. 236) have shown that the lime-avoiding Ericaceæ and other plants they examined suffer from lime only when this is associated with a large amount of soluble salts, and that root-formation fails when nutritive salts are in abundance in the presence of lime. Rhododendrons, however, do not appear to have been among the plants examined.

In connection with their behaviour towards lime-containing soils, plants may be roughly divided into two groups: of those which avoid lime, the heath family affords one of the most striking examples, but, contrary to expectation, certain members of the family, as, for instance, *R. hirsutum*, are characteristic plants of limestone districts.

It seems probable from the evidence now before us that some of Forrest's newly discovered Chinese rhododendrons, as also the one found by Lady Wheeler-Cuffe, must be reckoned as lime-loving species, but in all these cases the interesting question as to the quantity of lime absorbed by the plants growing on limestone rock still awaits an answer. Under natural conditions these lime-loving rhododendrons are flourishing on what we should consider a very sterile medium, and it may be that the poor growth which such plants exhibit when grown in lime-containing soil in our gardens is due to the superabundance of soluble nutritive salts, which may cause the lime to react unfavourably on the mycorrhiza of the roots, and that, under certain chemical conditions, the lime may have a definitely toxic influence. A. W. H.

## NOTES.

At a meeting of the council of the National Museum of Wales held at Cardiff on October 28, it was announced that a sum of 10,000*l.* had been received in War Loan Scrip from Capt. W. R. Smith, senior partner of the firm of W. R. Smith and Son, Cardiff, and Mrs. Smith towards the building fund of the new museum. The generous donors had made this gift in the belief that the National Museum would be one of the first educational influences in the Principality. There were other donors, who wished to remain anonymous for the present, and it is expected that when the present contract has been paid there will be a balance of about 16,000*l.* towards the 50,000*l.* which is needed to complete the furnishing and equipment of the portion of the building at present in course of erection.

Dealing with the fine collection of statues of eminent Welshmen at Cardiff unveiled by Mr. Lloyd George, a correspondent, writing in the *Western Mail*, points out with regret that no man of science figures in the series. He says that Robert Record, of Tenby, who flourished in the first half of the sixteenth century, might well have been included. Record was a man of cyclopædic knowledge, and was most eminent in his time, though little known to modern Welshmen. The use of the sign = to denote equality was introduced by him in 1557. He was "the first mathematician who wrote on arithmetic in English; the first who wrote on geometry in English; the first who introduced algebra into England; the first who wrote on astronomy and the doctrine of the sphere in English; and, finally, the first Briton (in all probability) who adopted the system of Copernicus." As a statue or two are still to be added, perhaps science may yet be represented in the Welsh Valhalla.

LORD RAYLEIGH presided at a meeting held at University College, London, on Tuesday, October 31, to take steps to establish a memorial to the late Sir William Ramsay. Mr. J. A. Pease, M.P., Postmaster-General, in moving that a memorial fund should be raised, to be utilised in promoting chemical teaching and research, under a scheme to be approved hereafter, said he was glad on behalf of the Government to pay a tribute to the memory of Sir William Ramsay and to take part in the great object of the meeting. The memorial should be not merely national, but international. Sir J. J. Thomson seconded the motion, which was supported by the Belgian Minister, who wished to convey the respectful homage of Brussels University, and by Mr. W. H. Buckler, who testified to the interest of the American Ambassador and his countrymen in the movement. The resolution was carried. It was also agreed that the meeting should resolve itself into a general committee, with Lord Rayleigh as chairman, to raise the necessary fund, and an executive committee was appointed to circulate an appeal.

A NEW departure in the study of Indian phonetics and linguistics is marked by the presentation before the Royal Asiatic Society, by Sir G. Grierson, head of the Linguistic Survey of India, of a series of gramophone records of four languages of the Munda group, prepared under the orders of the Government of Behar and Orissa. These comprise the Kharia, Mundari, Ho, and Santali, and one of the Dravidian group, Kurukk. In each case a version of the tale of "The Prodigal Son" has been reproduced, with some marriage songs and items of folklore. The work is important because the Munda tongues are a widespread group, extending through India proper to Assam, Burma, thence to Indo-China and the Malay Peninsula, and eastward to Easter Island. A copy of these records will be deposited at the India Office Library, a second in the British Museum, and a third in the rooms of the Asiatic Society. It is significant that this new record of phonetics is produced just as the first director of the School of Oriental Studies has been appointed. It may be hoped that similar records for other Indian languages may be prepared, and the scheme might be extended to other languages taught in our schools.

THE Chinese Government is becoming alive to the need for a proper geological investigation of the mineral resources of the country, and the lead in this task has been entrusted to Swedes. As the head of the survey, Dr. J. G. Andersson, formerly chief of the Swedish Geological Survey, has been appointed, and with him already are Dr. Tegengren and Prof. U. Nyström. We now learn that Dr. T. G. Halle, assistant in the palæobotanical department of the Riksmuseum at Stockholm, is to travel in China for one year, mainly in the interests of his own department, for which he will collect Palæozoic plants, but partly for the Chinese Government, to which he will report on the age and character of the coal-seams inspected, and for which a duplicate series of fossils will be provided after their determination. A young Chinese geologist will accompany Dr. Halle, and will be trained by him as a palæobotanist. The spring and summer will be devoted to the northern provinces, especially Shansi, with its enormous deposits of anthracite and ordinary coal. The coal-field of greatest scientific interest lies round and south of the Yangtse river, but how far this can be visited must depend on political conditions, now considerably disturbed. The expenses are borne by friends of the Swedish museum, but naturally every assistance will be given by the Central Government at Pekin.

A PAPER on food economics, by Prof. G. Lusk, in the Journal of the Washington Academy of Sciences for June 19, is worthy of study by everyone, and especially by those sending parcels of foodstuffs to prisoners in Germany. Prof. Lusk describes briefly how Germany tackled the all-important question of foodstuffs at the outbreak of the war. In order to maintain the protein portion of the nation's food the committee of investigation recommended that considerable increase should be made in the bean crop in Germany. Modifications were put forward in connection with the production of cereals, cheese, and skim milk, and it was finally concluded that the German people, through the co-operation of millions of inhabitants, would be able to obtain a ration of 3000 calories per adult per day, and so escape suffering from lack of food. A prisoner of war, doing moderate work, could get along on a ration of 2500 calories, composed as follows:—Proteins, 100 grams; carbohydrates, 400 grams; fats, 50 grams. On the assumption that a gram (roughly 15½ grains) of protein yields 4·1 calories, and that the corresponding values for carbohydrates and fats are 4·1 and 9·3 respectively, it is obvious that the total caloric value of this ration is about 2500. Prof. Lusk points out that true food reform demands the sale of food by calories and not by pounds, and he gives an instructive table of various articles of food, showing the weight and price of each necessary to produce 2500 calories. The following are some of the foodstuffs mentioned, and their costs in New York:—Oatmeal, 1 lb. 5⅓ oz., 2½*d.*; wheat flour, 1 lb. 8 oz., 3*d.*; sugar, 1 lb. 5⅓ oz., 3½*d.*; rice, 1 lb. 8½ oz., 3½*d.*; bread, 2 lb. 1 oz., 4*d.*; lard, 9½ oz., 4½*d.*; potatoes, 8 lb. 1 oz., 8*d.*; raisins, 1 lb. 12 oz., 10½*d.*; cheese, 1 lb. 3 oz., 11½*d.*; butter, 11 oz., 12*d.*; cocoa, 1 lb. 1 oz., 14½*d.*; lentils (dried), 1 lb. 8 oz., 15*d.*; salt cod, 6 lb., 45*d.*

OFFICERS of the Royal Artillery and the Royal Engineers, besides a large circle of friends in the teaching profession, will learn with deep regret of the sudden death, on October 18, of Mr. C. S. Jackson, Instructor of Mathematics and Mechanics at the Royal Military Academy, Woolwich. Before entering as a scholar of Trinity College, Cambridge, Mr. Jackson was head of Bedford School. He was eighth Wrangler in 1889, in the following year took the premier place in Part II. of the Law Tripos, and was called to the Bar shortly afterwards. In 1891 he joined the staff of the R.M. Academy, and for the past twenty-five years worked there with rare distinction and single-hearted devotion. He was a member of the council of the Mathematical Association, and took a prominent part on the various committees of that body, the reports of which have done so much to improve the mathematical teaching of our schools. He was also the first president of the London branch of this association. His great knowledge of the educational requirements of the country was recognised by the Board of Education when, in connection with the International Congress of Mathematicians, which met at Cambridge in 1912, it was determined to issue a series of reports dealing with the teaching of mathematics in secondary schools. The organisation of the work in connection with these reports was put into the hands of Mr. Jackson, and they form a lasting tribute to his far-sighted outlook on mathematical education. His work at Woolwich brought him into contact with the applications of mathematics to the problems of gunnery and military engineering. Working on these lines, he became a pioneer in breaking down the barrier that so long existed between so-called rational mechanics, as taught in our schools, and mechanics as applied to the problems of civil and military engineering.

THE *Nieuwe Courant* reports the death, at sixty-three years of age, of Prof. A. Torp, of the University of Christiania, the most famous of Norwegian philologists.

ACCORDING to the *Chemisch Weekblad*, the Bakhuis Roozeboom medal has been awarded to Prof. Schreinemakers, professor of inorganic and physical chemistry in the University of Leyden.

WE notice with much regret, in the *Times* of October 30, the announcement of the death, at seventy-seven years of age, of Prof. Cleveland Abbe, the well-known meteorologist of the U.S. Weather Bureau, Washington, D.C

THE Horace Dobell lecture of the Royal College of Physicians of London will be delivered by Dr. H. R. Dean on November 7. The subject will be "The Mechanism of the Serum Reactions." On November 14 and 16 Dr. W. H. R. Rivers will give the Fitz-Patrick lectures on "Medicine, Magic, and Religion" (part 2).

DR. E. D. VAN OORT'S report on the activities of the State Museum of Natural History at Leyden for the year ended September 1, 1916, records the transference of the collections to the new building in the Van der Werf Park, but laments that even now the collections are totally inaccessible to the public at large, owing to the lack of any exhibition galleries. The retirement, after forty-five years' service, of Dr. C. Ritsema Czn, keeper of the entomological collections, is a great loss to the museum. He is succeeded by R. van Eecke.

OWING to the pressure of his duties at Columbia University, Prof. M. H. Whitaker has resigned the editorship of the *Journal of Industrial and Engineering Chemistry*, one of the official organs of the American Chemical Society. He will be succeeded in that post by the president of the society, Prof. C. H. Herty, who will relinquish at the end of the year his duties as head of the department of chemistry at the University of North Carolina in order to devote his whole time to editorial work.

THE death is announced, in his seventy-fifth year, of Dr. Albert J. Cook, professor of zoology and entomology at the Michigan Agricultural College from 1866 to 1893, and afterwards professor of biology at Pomona College, California. From 1894 to 1905 he superintended the university extension work in agriculture in connection with the University of California. Prof. Cook is said to have been the first to make kerosene emulsion (in 1877), and to demonstrate and advocate the use of the arsenites as a specific against the codling moth (in 1880). He was the author of a manual of the apiary, and also of publications on "Injurious Insects of Michigan," "Silo and Silage," "Maple Sugar and the Sugar Bush," and "Birds of Michigan."

CAPT. J. O. WAKELIN BARRATT, who is serving with the British Expeditionary Force in France, writes:—"On October 17, at 9 p.m., an exceptionally fine lunar rainbow was visible in the west at Etaples (the moon had risen in the east). The width of the rainbow was fully equal to that of a solar rainbow, but no colour was recognisable, the rainbow being of a uniform light grey appearance." Full moon was on October 11—six days earlier—so that the atmospheric conditions must have been very favourable for a lunar rainbow to be distinctly visible. Such rainbows are usually faint, and their colours are not easily distinguished on this account. They generally have the appearance of a whitish or yellowish arch, except when the moon is full and other conditions are good, in which case colours may be seen, as in a solar rainbow.

THE sixth war course of Chadwick public lectures began on October 27 with a lecture on the physiological basis of fatigue by Prof. W. Stirling at the Royal Society of Arts. Prof. Stirling will give two other lectures on the effects of fatigue on industry and efficiency on November 3 and 10 at the same place at 5.15 p.m. Dr. C. Porter will deliver three lectures at Norwich Museum during November on the health of the future citizen. Dr. J. T. C. Nash will lecture at the Hampstead Central Library on November 20 on baby-saving for the nation; and Mr. P. Waterhouse will give three weekly lectures at the Surveyors' Institution, London, on architecture in relation to health and welfare, beginning on November 30. The lectures are free, and particulars concerning them can be obtained from the offices of the Chadwick Trust, 40 (6th) Queen Anne's Chambers, Westminster.

WE regret to note that *Engineering* for October 27 records the death, on October 7, of Col. T. Turrettini. Col. Turrettini was born in 1845, and his experience in hydraulic and electric machinery led to his election as one of the experts for the harnessing of the Niagara Falls in 1891. He was president of the Swiss National Exhibition held in Geneva in 1896. In the same number of *Engineering* is also recorded the death of Sir Henry Benbow, a prominent naval engineer officer of the past generation. In the Nile expedition of 1885 Sir Henry Benbow's name appears in the official despatch for his brilliant feat of repairing the boilers of the rescuing steamer under heavy fire, thus saving Sir Charles Wilson and his shipwrecked comrades. He was promoted to chief inspector of machinery in 1888, and was placed on the retired list at his own request in 1893.

SEVERAL further letters have reached us upon the subject of the scarcity of wasps during the past summer. The abundance of queen wasps referred to by correspondents last week seems to have been noticed in many districts. Mr. C. F. Butterworth, writing from Poynton, Cheshire, seven miles from Stockport, says:—"The queen wasps were much more numerous this year than I have known them during quite ten well-observed years, when I have kept honey bees and regarded these things with interest." Mr. K. Evershed, Kenley, Surrey, noticed a number of queen wasps in the spring, but adds, as to wasps in general:—"I do not recollect so marked a scarcity during the last thirty-five years in this county." Mr. V. E. Murray says that in the Reading district also their numbers have been considerably below the average. He adds:—"In July I observed early wasps on the flowers of Scrophularia (which they fertilise), and during the autumn, while engaged on a study of ivy, particularly as regards its fertilisation (in which they also take part), I have noticed a sprinkling of these insects obtaining honey from the discs of the flowers, this being the only occasion on which I have seen even a moderate number assembled. It was interesting to observe these wasps now and again preying on the numerous flies also attracted by the honey, bearing their victims to the ground and killing them after a short, fierce struggle. In one case when a wasp had finished feeding on a fly the head of the latter was found to have been severed from the trunk, and in another instance, when I disturbed a wasp killing a fair-sized fly, it flew off, carrying its prize bodily away!"

THE Harveian oration was delivered by Sir Thomas Barlow, at the Royal College of Physicians, on October 18. The story of Harvey's life and of his great

Digitized by Google

discovery of the circulation of the blood have often been told, and Sir Thomas Barlow dwelt on certain minor, but none the less important, details of Harvey's life before proceeding to consider Harvey as physician and as Court physician to Charles I., his Oxford life, his great discovery and work on generation, and his relations with the College of Physicians. Harvey was a pupil at King's School, Canterbury, and gained there a scholarship which enabled him to proceed to Caius College, Cambridge. The regulations for this scholarship, founded in 1571 by Matthew Parker, Archbishop of Canterbury, are probably unique for the period, and enjoined that the scholar should be educated first in subjects that pertain, or are serviceable, to medicine, and then in subjects which actually constitute medicine itself. In 1600 Harvey entered the University of Padua, and studied anatomy under the learned Fabricius, returning home in 1602, became a fellow of the College of Physicians in 1607 and attached to St. Bartholomew's Hospital, with which he was connected for thirty-six years. Sir Thomas Barlow's estimate of this side of Harvey's life is that, besides being a great anatomist and naturalist, he was an experienced pathologist, a learned physician, and had the qualifications of a good, all-round practitioner. The College of Physicians was the chief interest of his old age, and he enriched it with many benefactions. The last exhortation of the great master was "ever to search out and study the secrets of Nature by way of experiment, and for the honour of our profession to continue in mutual love and affection among ourselves."

SOME weeks ago there was considerable speculation as to the truth of the reports concerning Germany's new super-Zeppelins, and the matter was referred to in these columns. Since that date two Zeppelins of the very latest type have been brought down in England, and one in such a state of preservation that detailed information has been readily obtained from it. Excellent descriptions of this airship have appeared in the daily papers, and a particularly correct account in the *Times* for October 19. All the main particulars of the early reports are justified. The capacity of the L33 has been estimated at 2,000,000 cub. ft., its length at 680 ft., and the total horse-power at about 1500, which entirely confirms the figures previously given in these columns. More information is now available concerning the minor details of the new design. A point worthy of particular notice is the centralisation of the controls, the whole airship being under the control of the men in the forward gondola. Bombs and petrol tanks are carried in a passage-way along the keel of the ship, which also serves for communication between the various gondolas. The extent of the development of small details is illustrated by the fact that provision has even been made for dropping the petrol tanks in case of emergency, to save all possible lifting power. The bomb-releasing arrangements are exceedingly neat and trustworthy, and an armament of nine machine-guns has been provided. The construction of the main framework is very ingenious, the strength being enormous for the weight of metal used. In view of the great improvements in the design of these latest Zeppelins, it is comforting to think that our defensive measures have proved so successful against them, and that the raiders no longer enjoy the comparative immunity from loss which characterised the earlier raids.

WE have received the report of the Director-General of Public Health, New South Wales, for the year ended December 31, 1915. The report contains, in addition to the usual statistical information, the report of investigation and research work of the microbiological laboratory. The routine examination of rats and mice for plague infections forms a part of the work of this laboratory, and it is of interest that no plague infection has been found since 1910 among these rodents, although some 60,000 animals have been examined during the years 1911–14 inclusive.

PHYSICIANS and psychologists will find a critical discussion of the value and limitations of the intelligence tests in diagnosing the mind of a child, in the *Psychological Review* (vol. xxiii., No. 5). The writer, Mr. J. V. Haberman, finds the Binet method entirely inadequate to furnish an accurate or truthful equation of the general intellectual ability of an individual, and, further, insists that even if general ability were so tested it would be of no diagnostic value to the psychopathologist, since in mental pathology the processes involved are not always of the nature of general ability, but of mental functioning. He suggests a method of testing which shall serve in diagnosis, prognosis, and prophylaxis, and that shall give a clue to therapy and remediable pedagogic processes. He also points out that this testing should not be in the hands of the psychologist only, but of a physician with a psychological training. The increasing importance now being attached to tests renders the criticism of an expert pertinent and valuable.

IN the numbers of *Scientia* for September and October, 1916, Prof. Eugenio Rignano writes the two parts of an elaborate and interesting psychological study of what he calls "intentional" reasoning. In *Scientia* during last year he published several articles concerned with the psychological analysis of reasoning, and the present contributions complete this analysis. In the reasoning previously considered, the reasoner, at least at the moment when he begins his reasoning, has no intention to support certain theses at the expense of certain others, but only that of discovering the truth. On the other hand, the "intentional" reasoner sets about reasoning for the purpose of proving the correctness of definite assertions which he has at heart. Prof. Rignano's work is divided into two main parts, which deal with the two chief varieties of "intentional" reasoning: dialectical reasoning and metaphysical reasoning. The latter part is subdivided into sections on metaphysical theology; metaphysics properly speaking; finalism, animism, and vitalism; the function of language in metaphysical reasoning; and positivism and metaphysics. These researches are particularly interesting at the present time, when the attention of many philosophers and men of science is fixed on scientific method in philosophy, and some philosophers are gradually coming to recognise in their work that in philosophy, just as in what is usually called science, only an unbiassed search for truth is really legitimate and can lead to permanent results. Of course, this seems a truism when stated thus as a maxim of method, but it is none the less a fact that philosophers have not, as a rule, hitherto worked in accordance with it.

DR. W. D. MATTHEW, in the Bulletin of the American Museum of Natural History (vol. xxxv.), describes in great detail "A Marsupial from the Belly River Cretaceous." The remains forming the subject of this communication comprise no more than the left ramus of the mandible, the symphysis of the right mandible, and fragments of the cranium, but they constitute the most complete remains of fossil mam-

Digitized by Google

mining a Ceratopsian skull, beneath which it lay. Being thus accidentally found during work with a heavy pick, it was badly shattered, but it is believed that all the fragments originally preserved have been recovered.

MR. E. C. CHUBB, the curator of the Durban Museum, is to be congratulated on the admirable "General Guide" which he has prepared for the aid of visitors, a copy of which has just reached us. Mr. Chubb has evidently made the most of the collections under his charge, though it would seem that great gaps have to be filled, even in so far as African mammals are concerned. If we may judge from this guide, neither the elephant nor the giraffe is yet represented here. When a new edition of this guide is issued we would suggest that the statement that the "lamp-shells," or Brachiopods, are possibly related to the starfishes should be corrected, while in regard to the information concerning flexible sandstone the fact might be added that it is found in India and Brazil. At the present time the Durban Museum occupies no more than the first floor of the south block of an imposing pile of buildings serving also as an art gallery and public library, and apparently yet other functions. In the course of time it is to be hoped the Natural History Department will either oust its rivals or find new and more commodious quarters elsewhere; as matters stand, the space allotted to it is inadequate.

MR. E. P. MEINECKE, in U.S. Dept. Agric. Bulletin, No. 275, entitled "Forest Pathology in Forest Regulation," gives the results of an investigation, as regards the incidence of wounds and disease, of 160 felled trees of *Abies concolor*, varying in age from 60 to 258 years. These trees were representative of the ordinary condition of the species under natural forest conditions in Oregon. Only one-fourth of the trees were found to be free from wounds. The rest had all been injured at one time or another by lightning, fire, frost-crack, etc., or by a combination of these, and as the wounds permitted infection by fungi, decay had set in. After the trees had reached eighty or ninety years of age, 70 per cent. were more or less badly wounded; and at 106 years, 80 per cent.; but serious decay of the timber rarely set in until about the age of 130 years. Fire, usually caused by lightning, is the greatest enemy. The management of the forest should be modified by the pathological conditions, as it is evident that much may be done to avert decay and destruction of valuable timber by timely removal of wounded and badly suppressed trees, and by fixing the felling rotation at 130 to 150 years.

THE richness of Sweden in water-power, and Denmark's natural poverty in any sources of power, has led to Sweden exporting electric power across the Sound. The works are established in the small river Lâga, in Småland, and the current is carried by overhead wires to Helsingborg, and thence by three submarine cables under the waters of the Sound to Marienlyet, north of Elsinore, on the island of Seeland. According to *La Géographie* (vol. xxxi., No. 2), the Swedish power station sends 500 h.p. to Denmark, but the company undertakes to increase this to 5000 h.p. Precautions have been taken so far as possible to prevent the cables being fouled by the anchors of ships.

THE Royal Italian Geographical Society has issued as one of its special memoirs a handbook and index to the names which appear on the Austrian Staff map (1 : 75,000) of the Alto Adige, the new province of Italy lying north of the Trentino ("Prontuario dei nomi locali dell' alto Adige"). The index itself, apart from the introduction, runs to more than one hundred pages, and contains all the names on the fourteen sheets of the map, with their Italian equivalents. Pending the preparation of a new map, this index should be of great value, as many of the places are difficult to identify from the German versions of their names, which often bear no relation to the Italian. The work has been done under the direction of Signor E. Tolomei.

WITH the view of increasing the commercial utility of cobalt, Dr. H. T. Kalmus, of Queen's University, Kingston, Ontario, has carried out a number of investigations of the physical properties of the metal and its alloys for the Mines Branch of the Department of Mines of Canada. The fifth of these investigations deals with the magnetic properties of pure cobalt and of the alloy $Fe_2Co$, and has been conducted by Dr. Kalmus and Mr. K. B. Blake. The B, H curves of both materials have been obtained by the Burrows method in use at the American Bureau of Standards. For pure cobalt the value of B for H = 100 is only about 5000, while older observations had given 8000. At H = 150 B has risen to 6300, and shows no sign of the material being magnetically saturated. The $Fe_2Co$ alloy, when cast, is very liable to fine cracks, but after forging is more than twice as strong as pure iron. At low fields its magnetic permeability is less than that of pure iron, but at fields exceeding 8 it is greater, and for fields of the order 50 to 200 is approximately 25 per cent. greater. The hysteresis loss is considerably less than that of transformer steel, and its electrical resistance about the same as that of pure iron.

A PAPER by the late Lieut. F. Trevor Wilkins (Northumberland Fusiliers), read at the Institution of Mechanical Engineers on October 20, gives an account of some trials of a small Diesel engine at the University of Birmingham. The manner of conducting these trials and reducing the results enabled figures to be presented additional to those usually given in such investigations. The indicator diagrams have been redrawn upon a heat-energy chart, and by this means any differences between the theoretical and practical cycles are clearly exhibited. The amounts of heat passing to the cylinder walls and to the exhaust were determined accurately. The heat flow during the compression and expansion strokes was estimated separately, and the period during which this heat flow takes place was indicated definitely. At full load the thermal efficiency, heat to jackets, and heat to exhaust are respectively 42·1, 29·6, and 28·3 per cent., these being the results of the test. The corresponding figures from the energy diagrams are 42·5, 25·3, and 32·2 per cent.

## OUR ASTRONOMICAL COLUMN.

THE FIREBALL OF OCTOBER 20.—Mr. Denning writes that forty-six observations of this brilliant object have reached him. It was seen from widely distant stations, the most northerly being Rothes (Elgin), and the most southerly Totteridge (Herts) and Bristol. The fireball was a splendid one, and it traversed a long flight of about 252 miles, from over a place 60 miles N.W. of Edinburgh to 50 miles E. of Whitby, Yorks. Its elevation decreased from 68 to 25 miles, and its velocity was about 17 miles per second. The radiant point was near ζ Herculis, situated low in the N.W. by W. sky at the time of the apparition. There is no well-known meteor shower from this region in the autumn, but bright meteors have sometimes been observed from the same astronomical point at various times of the year, and this point near ζ Herculis forms the chief focus of a well-defined meteoric shower visible during the last half of May.

Digitized by Google

THE ORIONID SHOWER OF 1916.—These October meteors were fairly well seen this year between October 20 and 25 at Bristol. There were two showers, one at 92°+15°, the true Orionids, and a richer one at 98°+14°, near γ Geminorum. These results appear to substantiate observations made in 1900 and 1903 at Bristol, when the Geminids exhibited greater activity than the Orionids. The two showers, lying so near together, are very liable to be confused; in fact, in some cases it is impossible to say to which radiant the meteors are conformable.

Of the other showers belonging to this usually prolific meteoric epoch, only a few of well-pronounced character were visible this year. There were, however, some slow meteors from a sharply defined radiant at 72°+66°, and some very swift, streaking meteors from a point at 121°+43°. Several of the true Orionids, observed on October 20, were recorded at two stations, and their real paths have been computed.

ULTRA-VIOLET RADIATION FROM THE SUN.—Prof. Birkeland has recently given an account of some observations of the zodiacal light, and of the registration of the ultra-violet radiation of the sun (*Cairo Sci. Journ.*, vol. viii., p. 287). The most effective rays of the zodiacal light appear to have a wave-length of about 3200 A.U. and under, so that, in attempts to obtain photographs, lenses of quartz, or mirrors of Mach's metal (67 Al+33 Mg) or of nickel, should be employed. Regarding the zodiacal light as a manifestation of the general electrical activity of the sun, Prof. Birkeland was led to investigate the ultra-violet radiation of the sun itself by the use of a filter consisting of a silver film which was opaque to visible light. Sunbeams transmitted through such a film were received by a photo-cell and registered in the usual manner. Variations of intensity were observed, and there was some slight evidence of a relation to changes in horizontal magnetic intensity. While allowing that some of the observed variations of the ultra-violet intensity were probably due to atmospheric differences, Prof. Birkeland finds reason to believe that variations also arise through real changes in the electrical state of the sun. The possibility of extending such observations to stars and planets by the use of large concave mirrors, say 4 metres in diameter, is suggested. A new analysis of celestial bodies giving information as to their general electrical states, might thus be founded.

## THE SOIL SURVEY OF WISCONSIN.[1]

FOLLOWING the lead set by the American Bureau of Soils, the State of Wisconsin has arranged for a soil survey, and is publishing the results in a series of attractive booklets, well provided with maps, diagrams, and illustrations. First of all, there was issued in 1911 the so-called "Reconnaissance Soil Survey of Part of North-West Wisconsin," in which a general account was given of the geology, climate, soil, and agriculture of the area. This has now been followed by more detailed accounts of the various counties. It is proposed to complete the work by issuing a series of bulletins dealing with the management of the different types of soil, and on the 1-in. maps issued with these reports the various soil types are so clearly defined that the farmer would have no difficulty in locating his land, and so discerning which particular bulletin would give him advice as to cropping and management.

The region lies wholly within the great Mississippi valley, and its main topographical feature is the relatively level or gently-sloping surface of the land. Like other parts of the valley, it is an undulating plain into which lesser valleys have been cut by the rivers and streams.

The underlying rocks belong to the Cambrian or pre-Cambrian systems, and include crystalline rocks, sandstone, and limestone (mainly magnesian limestone). But on the whole the soils are not derived from the rocks immediately below them. Upon the broad uplands are extensive deposits of Glacial drift which in many cases retain the general forms left by the great ice-sheets that invaded this region. The lakes are here intimately related in origin to the Glacial deposits. There are also extensive wind deposits of loess over large portions of the uplands. In many of the valleys are thick deposits of loose sand and gravel, which assume the form of terraces.

The climate is not influenced by the Great Lakes, but it is by the storms that move eastward along the Canadian border and those that drift up the Mississippi valley from the south-west. As in other parts of the northern Mississippi valley, extremes of temperature prevail, the summer being warm, with abundant rainfall, and the winter cool and relatively dry. The mean temperature of the summer months is about 65°–70° F.; in January and February about 10° F.; the extremes range from about 105° F. in the summer to −48° F. in winter.

Originally the land was covered with hardwood and pine, the latter being especially abundant on the sandy lands along the rivers. Much of this still remains, and there is considerable land available for agricultural settlement. Only in the west of the area do the thinly wooded and prairie lands occur.

The first settlers after the explorers and fur-traders were lumbermen, and their way into the country was by boat on the Chippewa River. But fifty or sixty years ago the agricultural settlement began, and now all the ordinary crops are raised in quantity, oats being the most important cereal, followed by maize, barley, and wheat. Among the special crops cultivated in certain districts are potatoes, sugar-beets, tobacco, peas, and maize for canning. Dairying is a particularly important industry; and it has further given rise to the well-known researches of Woll on feeding problems, and of Babcock and Russell on the composition of milk and the estimation of fat.

Typical analyses are given of the various soil types; as usual in the States, they are almost wholly mechanical analyses, only very few chemical data being given. In studying the results it must be remembered that the terms have very different meanings from those assigned to them in this country. The substances indicated by the analysis owe their properties to their sizes, and therefore the names given to them are intended simply to define the diameters of the particles, but unfortunately no international agreement has yet been reached, and hence the same name is used in different countries for wholly different-sized particles. Thus the terms have the following meanings in American and British surveys respectively:—

*Mean diameter of particles, mm.*

| | United States | Great Britain |
|---|---|---|
| Fine gravel ... | 2 –1 ... | Above 1 |
| Coarse sand ... | 1 –0·5 ... | 1 –0·2 |
| Medium sand ... | 0·5 –0·25 ... | Not used |
| Fine sand... ... | 0·25–0·10 ... | 0·2 –0·4 |
| Very fine sand... | 0·10–0·05 ... | Not used |
| Silt ... ... ... | 0·05–0·005 ... | 0·04–0·01 |
| Fine silt ... ... | Not used ... | 0·01–0·002 |
| Clay ... ... ... | Below 0·005 ... | Below 0·002 |

Direct comparison with British soils is therefore impossible, a circumstance much to be regretted, as in

[1] Wisconsin Geological and Natural History Survey: Bulletins 28–32 Soil Series, Nos. 2–6), and Bulletins 37–40 (Soil Series, Nos. 7–10).

Digitized by Google

many cases the comparison would undoubtedly prove interesting. But fortunately the descriptions are so good that the student loses less than might be expected, and the results are very valuable, not only to the farmers for whom they were intended, but also to the student of soil problems all over the world.

E. J. R.

## THE SCIENTIFIC WORK OF A SCHOOL OF TECHNOLOGY.

THE eighth volume of the Record of Investigations undertaken by members of the Manchester Municipal School of Technology, covering technological researches carried out during the year 1914, has just been issued. It is a highly interesting record of work accomplished, and is comprised in 258 quarto pages replete with explanatory diagrams and photographs illustrative of the text. This attempt to put upon permanent record the investigations conducted by members of the staff and by advanced students was begun in 1905, and has now extended to 2346 pages, and in its eight volumes covers researches carried out since the year 1900 in all departments of the school, including pure and applied mathematics, mechanical engineering, physics and electrical engineering, pure and applied chemistry and metallurgy, the science and practice of sanitation and building, textile manufacture, and the photographic and printing industries.

For investigations in all these important departments of industrial enterprise the school is exceptionally well equipped, and it has, moreover, had the assistance of many enlightened manufacturers, and in this connection many considerable extensions are in contemplation, only awaiting the conclusion of the war to give them full effect. Meanwhile new laboratories for advanced training and research in the subject of coal-tar chemistry in its bearing upon the dye-stuff industry have been opened under the charge of Prof. A. G. Green, of the University of Leeds, with the help and advice of Dr. E. Knecht, the professor of chemical technology, thus giving full opportunity, not only for the efficient training of chemists for the growing demands of the organic chemical industries, but for the establishment of a school of research for the chemistry of dyes and allied substances employed in industrial chemistry.

Many of the articles and researches published in these journals have also appeared in the scientific and technical Press. Lists are also given of important papers read in connection with the various technical societies connected with the school, including the Engineering Society, the Day Students' Chemical Society, the Textile Society, which itself publishes an important journal, the Printing Crafts Guild, and the Bakery and Brewing Students' Societies, together with the titles of fifty-four theses prepared by graduate students in technology for the degree of M.Sc.Tech. in the University of Manchester. Lists also appear of the titles of nearly fifty volumes of technical works issued by members of the staff since 1900.

The eighth volume of the journal under review contains, among other articles of value, interesting papers concerned with the applications of chemical science, such as those on vulcanising, industrial gas-burning, the action of strong nitric acid upon cotton cellulose and of sulphuretted hydrogen upon sodium hydrosulphite, together with papers on the dilution limit of inflammability of gaseous mixtures and on the ignition of gaseous mixtures by the electric discharge. Not the least valuable paper is one entitled "A Contribution to the History of Dyeing in Scotland," being a sequel to one in vol. vii. of the journal on the history of dyeing suggested by a remark of the late Prof. Meldola in his presidential address of 1910 to the Society of Dyers and Colourists on "The Antiquity of Tinctorial Art": "I have in mind the desirability of technical societies such as ours including in their work the antiquarian side of their subject. This is, as a rule, neglected. Nevertheless, it is desirable to secure records of the past with respect to ancient industries, and the experts in any particular subject are assuredly the right people to undertake such work." Other important articles in the current number deal with researches on the ultimate endurance of steel and of the results of experiments with lathe-finishing tools, a continuation of valuable experiments and investigations begun in the school so far back as 1903 on high-speed tool steels and cutting tools, which are even now under investigation; on modern boiler-room practice and the prevention or abatement of smoke; on the effect of structure on the strength and wearing qualities of cloth, copiously illustrated; on a null method of testing vibration galvanometers; and on the commutation of large continuous-current generators and rotary converters under heavy-load conditions.

The school is thus "an excellent example of the kind of work which the engineering colleges and the higher technical schools in this country ought to undertake, and must be prepared to perform, if they are to occupy the place of similar institutions abroad in the very important matter of practical research, not merely as teaching young men the elements of technical science, but also as establishments where industrial experiments can be carried out on a practical scale." It only remains to say, as exhibiting the great resources of this school, that the journal has been admirably printed and its illustrations prepared at the school press.

## PHYSIOLOGY AT THE BRITISH ASSOCIATION.

THE attendance of physiologists at the Newcastle meeting was comparatively small, but there was a good programme, and several of the papers elicited considerable discussion. Prof. Cushny, the president of the section, took a pharmacological subject for his address. Reports of research committees were then presented, and Prof. Waller exhibited a simple apparatus for the administration of known percentages of chloroform. The recent modifications suggested by the extensive use of the instrument were described.

A series of lantern-slides illustrating the action of pituitary extract on the secretion of cerebro-spinal fluid was shown by Prof. Halliburton. The increased secretion is claimed by him to be an indirect result of the extract, the immediate cause being ascribed to stimulation of the cells of the choroid plexus by an increased quantity of $CO_2$ in the blood.

Prof. W. H. Thompson detailed the results of further investigations into the formation of arginine and creatine. An interesting paper by Prof. Cushny on the secretion of urea and sugar by the kidney was the outcome of a repetition of Heidenhain's experiments, with this difference, that urea in some experiments, and sugar in others, were injected instead of a dye into the blood of an animal after transection of its spinal cord. Analysis of the kidneys after a suitable interval showed no increase of urea or sugar in them above the normal, and there was therefore no accumulation of these substances in the cells of the convoluted tubules.

Prof. Herring gave the results of several series of experiments in which white rats had been fed on small

Digitized by Google

doses of fresh thyroid for various periods of time. The administration of 0·2 gram of fresh ox thyroid in the food daily for one month led to a 75 per cent. increase in the weight of the suprarenals, and a 50 per cent. increase in their adrenalin content. Further, there was great hypertrophy of the heart, especially of the ventricles, the weight of the heart being double, and in some nearly treble, the weight of the heart of control animals. The kidneys were also enlarged, though not to the same extent. Prof. Herring directed attention to the similarity in the condition produced in white rats by small amounts of thyroid to the condition sometimes found in "soldier's, or trench, heart" in man, and suggested that cardiac hypertrophy, associated with excessive production of adrenalin and changes in other organs, might sometimes be caused in man by over-action of the thyroid glands. A paper by Dr. Kojima followed, in which changes in the pancreas induced by thyroid-feeding were illustrated by lantern-slides. The pancreas of thyroid-fed animals showed numerous karyokinetic figures, and alterations in the amount of secretory granules in the cells.

In the discussion which followed these two papers Sir William Osler, Sir Edward Schäfer, Prof. Drummond, and Prof. Moore took part.

On Friday morning, September 8, Dr. Itagaki described the action of ovarian extracts, more especially of luteal tissue, on preparations of uterine and intestinal muscle.

A paper by Prof. Bayliss on "The Properties Required in Solutions for Intravenous Injection" was read, in which the author recommended the use of a 7 per cent. solution of gum acacia. Such a transfusion fluid has a viscosity, and exerts an osmotic force, more nearly resembling blood plasma than normal saline, and when used in cases of hæmorrhage gives better results.

Prof. Moore and Mr. Barnard gave a paper on the nutrition of living organisms by simple organic compounds.

The meeting closed with a discussion upon "Food Standards and Man Power," introduced by Prof. Waller. The object of the discussion was to prepare the way for the formation of a committee to formulate definite figures for the value of work done by man, woman, and child.

## THE BRITISH ASSOCIATION AT NEWCASTLE.

### SECTION H.

#### ANTHROPOLOGY.

OPENING ADDRESS (ABRIDGED) BY R. R. MARETT, M.A., D.Sc., PRESIDENT OF THE SECTION.

THE question to which I beg to direct attention on the present occasion is: What function ought anthropology to fulfil among the higher studies of a modern university? The subject may be commonplace, but it is certainly not untimely. At the present moment those of us who are university teachers in any of the warring countries are feeling like fish out of water. Our occupation is to a large extent suspended; and already it seems a lifetime since we were assisting, each after his own fashion, in the normal development of science.

"Usus abit vitæ: bellis consumpsimus ævum."

Can the hiatus be bridged, the broken highway mended? Never, if memories are to prevail with us; but if hopes, then it goes equally without saying that we shall somehow manage to carry on more actively and successfully than ever. So the only problem for brave and hopeful men is, How? Ignoring our present troubles, we are all thinking about the future of university education, and reform is in the air.

Of course, every university has difficulties of its own to meet; and my own University of Oxford, with eight centuries of growth to look back on, is likely to be more deeply affected by the sundering of traditions due to the war than such of its sister-institutions as are of more recent stamp. Now, when I discuss university matters, the case of Oxford is bound to weigh with me predominantly; and, indeed, no man of science could wish me to neglect what, after all, is bound to be my nearest and richest source of experience. But various kind friends and colleagues hailing from other universities in Great Britain, France, and the United States have furnished me with copious information concerning their home conditions, so that I shall not altogether lack authority if I venture to frame conclusions of a general nature. Besides, it is not on behalf of any university, but rather as representing the interests of the science of anthropology, that I am entitled to speak in my present capacity. I do indeed firmly hold that anthropological teaching and research can be admitted to the most ample status in the curriculum of any modern university without injury to established industries and activities. But, even if this were not so—even if it needed a sort of surgical operation to engraft the new in the old—we anthropologists must, I think, insist on the fullest recognition of our science among university studies, realising, as we are especially able to do, its immense educational value as a humanising discipline. Let me not, however, rouse prejudice at the outset by seeming to adopt an aggressive tone. "Live and let live" is the safest motto for the university reformer; and I have no doubt that the peaceful penetration whereby anthropology has of late been almost imperceptibly coming to its own in the leading universities of the world will continue to accomplish itself if we, who make anthropology our chief concern, continue to put forth good work in abundance. For, like any other science, the science of man must be justified of its children.

Now, it is customary to contrast what are known as technical studies with university studies proper; and such a distinction may prove helpful in the present context, if it be not unduly pressed. Thus, in particular, it will afford me an excuse for not attempting to travel afresh over the ground covered by Sir Richard Temple in his admirable presidential address of three years ago. What he then demanded was, as he termed it, a school of applied anthropology, in which men of affairs could learn how to regulate their practical relations with so-called "natives" for the benefit of all concerned. Let me say at once that I am in complete agreement with him as to the need for the establishment or further development of not one school only, but many such schools in this country, if the British Empire is to make good a moral claim to exist. Indeed, I have for a number of years at Oxford taken a hand in the anthropological instruction of probationers and officers belonging to the public services, and can bear witness to the great interest which students of this class took at the time, and after leaving Oxford have continued to take, in studies bearing so directly on their life-work.

What I have to say to-day, however, must be regarded as complementary rather than as immediately subsidiary to Sir Richard Temple's wise and politic contention. The point I wish to make is that, unless anthropology be given its due place among university studies proper, there is little or no chance that technical applications of anthropological knowledge will

Digitized by Google

prove of the slightest avail, whether attempted within our universities or outside them. Anthropology must be studied in a scientific spirit—that is, for its own sake—and then the practical results will follow in due course. Light first, fruit afterwards, as Bacon says. So it has always been, and must always be, as regards the association of science with the arts of life. That Sir Richard Temple will heartily subscribe to such a principle I have no doubt at all. As a man of affairs, however, whose long and wide experience of administration and of the problems of empire had convinced him of the utility of the anthropological habit of mind to the official who has to deal with "all sorts and conditions of men," he naturally insisted on the value of anthropology in its applied character. On the other hand, it is equally natural that one whose career has been wholly academic should lay emphasis on the other side of the educational question, maintaining as an eminently practical proposition—for what can be more practical than to educate the nation on sound lines?—the necessity of establishing anthropology among the leading studies of our universities.

How, then, is this end to be attained? The all-important condition of success, in my belief, is that all branches of anthropological study and research should be concentrated within a single school. For it is conceivable that a university may seek to satisfy its conscience in regard to the teaching of anthropology by trusting to the scattered efforts of a number of faculties and institutions, each of which is designed in the first instance to fulfil some other purpose Thus for physical anthropology a would-be student must resort to the medical school, for social anthropology to the faculty of arts, for linguistics to the department of philology, for prehistorics to the archæological museum, and so on. Such a policy, to my mind, is a downright insult to our science. Is the anthropologist no better than a tramp that he should be expected to hang about academic back-doors in search of broken victuals? Fed on a farrago of heterogeneous by-products, how can the student ever be taught to envisage his subject as a whole? How, for instance, is he ever to acquire the comprehensive outlook of the competent field-worker? Such a makeshift arrangement can at the most but produce certain specialists of the narrower sort. In "The Hunting of the Snark" they engaged a baker who could only bake bride-cake. Anthropological expeditions have, perhaps, been entrusted before now to experts of this type; but they have not proved an entire success. I am not ashamed to declare that the anthropologist, be he field-worker or study-worker—and, ideally, he should be both in one—must be something of a Jack-of-all-trades. This statement, of course, needs qualification, inasmuch as I would have him know everything about something, as well as something about everything. But the pure specialist, however useful he may be to society in his own way, is not as a rule a man of wide sympathies; whereas the student of mankind in the concrete must bring to his task, before all else, an intelligence steeped in sympathy and imagination. His soul, in fact, must be as many-sided as that complex soul-life of humanity which it is his ultimate business to understand. . . .

It has sometimes been objected that, however much we strive by means of organisation to invest anthropology with an external semblance of unity, the subject is essentially wanting in any sort of inner cohesion. Nor does such criticism come merely from the ignorant outsider; for I remember how, when the programme for our diploma course at Oxford was first announced to the world, Father Schmidt found fault with it in the columns of *Anthropos* on the ground that it was not the part of one and the same man to combine the diverse special studies to which we had assigned a common anthropological bearing. In the face of such strictures, however—and they were likewise levelled at us from quarters nearer home—we persisted in our design of training anthropologists who should be what I may call "all-round men." Let them, we thought, by all means devote themselves later on to whatever branch of the subject might attract them most; but let them in the first instance learn as students of human life to "see it steadily and see it whole." Since this resolve was taken, a considerable number of students has passed through our hands, and we are convinced that the composite curriculum provided in our diploma course works perfectly in practice, and, in fact, well-nigh amounts to a liberal education in itself. It is true that it cuts across certain established lines of demarcation, such as, notably, the traditional frontier that divides the faculty of arts from the faculty of natural science. But what of that? Indeed, at the present moment, when the popular demand is for more science in education—and I am personally convinced that there is sound reason behind it—I am inclined to claim for our system of combined anthropological studies that it affords a crucial instance of the way in which natural science and the humanities, the interest in material things and the interest in the great civilising ideas, can be imparted conjointly, and with a due appreciation of their mutual relations.

Now, there is tolerable agreement, to judge from the university syllabuses which I have been able to examine, as to the main constituents of a full course of anthropological studies. In the first place, physical anthropology must form part of such a training. I need not here go into the nature of the topics comprised under this head, the more so as I am no authority on this side of the subject. Suffice it to say that this kind of work involves the constant use of a well-equipped anatomical laboratory, with occasional excursions into the psychological laboratory which every university ought likewise to possess. It is notably this branch of anthropology which some would hand over entirely to the specialist, allowing him no part or lot in the complementary subjects of which I am about to speak. I can only say, with a due sense, I trust, of the want of expert knowledge on my part, that the results of the purely somatological study of man, at any rate apart from what has been done in the way of human palæontology, have so far proved rather disappointing; and I would venture to suggest that the reason for this comparative sterility may lie not so much in the intrinsic difficulties of the subject as in a want of constructive imagination, such as must at once be stimulated by a fuller grasp of the possibilities of anthropological science as a whole.

In the next place, cultural, as distinct from physical, anthropology must be represented in our ideal course by at least two distinct departments. The first of these, the department of prehistoric archæology and technology, involves the use of a museum capable of illustrating the material culture of mankind in all its rich variety. Here instruction will necessarily take the form of demonstration-lectures held in the presence of the objects themselves. To a limited extent it should even be possible to enable the student to acquire practical experience of the more elementary technological processes, as, for instance, flint-knapping, fire-making, weaving, the manufacture of pottery, and so on. May I repeat that, to serve such educational purposes, a special kind of museum organisation is required? Moreover, it will be necessary to include in the museum staff such persons as have had a comprehensive training in anthropology, and are consequently competent to teach in a broad and humanising way.

The other department of cultural anthropology is one

Digitized by Google

that embraces a considerable complex of studies At Oxford we term this branch of the subject social anthropology, and I do not think that there is much amiss with such a title. Among the chief topics that it comprises are kinship- and marriage-organisation, religion, government, law, and morals. Further, economic and æsthetic developments have to be examined in their reference to the social life, as apart from their bearing on technology. In one aspect all these subjects lend themselves to a sociological method of treatment; and, though no one is more concerned than myself to insist on the paramount importance of psychology in the equipment of the perfect anthropologist, I would concede that the sociological aspect ought so far as possible to be considered first, as lending itself more readily to direct observation. To reveal the inner workings of the social movement, however, nothing short of psychological insight will suffice. Indeed, all, I hope, will agree that the anthropologist ought to be so trained as to be able to fulfil the functions of sociologist and psychologist at once and together.

It remains to add that no training in social anthropology can be regarded as complete that does not include the study of the development of language. On the theoretical side of his work the student should acquire a general acquaintance with the principles of comparative philology, and, in particular, should pay attention to the relations between speech and thought. On the practical side he should be instructed in phonetics as a preparation for linguistic researches in the field. But detailed instruction in particular languages, more especially if these are not embodied in a literature, is scarcely the business of a school of anthropology such as every university may aspire to possess. . . .

So much, then, for the multiplicity which an anthropological curriculum must involve if it consist, as has been suggested, of physical anthropology, technology with prehistoric archæology, and social anthropology with linguistics. And now what of its unity? How best can these diverse studies be directed to a common end? I would submit that there are two ways in which the student may most readily be made to realise the scope of anthropology as a whole, the one way having reference to theory and the other to practice.

The theoretical way of making it plain that the special studies among which the student divides his time can, and must, serve a single scientific purpose is to make his work culminate in the determination of problems concerning the movement of peoples and the diffusion of culture—in a word, of ethnological problems (if, as is most convenient, the term "ethnology" be taken to signify the theory of the development of the various ethnic groups or "peoples" of the world). A great impetus was given to the investigation of such matters by Dr. Rivers in a now famous presidential address to this section, followed up, as it was shortly afterwards, by a monumental work on the ethnology of the Pacific region. But it would be quite a mistake to suppose that anthropologists were not previously alive to the importance of the ethnological point of view as a unifying interest in anthropological theory. So far back as 1891, when the second Folklore Congress met in London, under the presidency of the late Andrew Lang, the burning question was how far a theory of diffusion and how far a theory of independent origins would take us in the explanation of the facts with which the science of folklore is more particularly concerned. It is true that there has been in the past a tendency to describe the theory of independent origins as the "anthropological" argument; but such a misnomer is much to be regretted. Anthropology stands not for this line of explanation, or for that, but for the truth, by whatever way it is reached; and ethnology, in the sense that I have given to the term, is so far from constituting the antithesis of anthropology that it is rather, as I have tried to show, its final outcome and consummation. Recognising this, the Oxford School of Anthropology from the first insisted that candidates for the diploma should face an examination paper in ethnology, in which they must bring the various kinds of evidence derived from physical type, from arts, from customs, and from language to bear at once on the problem how the various ethnic individualities have been formed. The result, I think, has been that our students have all along recognised, even when most deeply immersed in one or other of their special studies, a centripetal tendency, an orientation towards a common scientific purpose, that has saved them from one-sidedness, and kept them loyal to the interests of anthropology as a whole. Let me add that, as our anthropological course ends in ethnology, so it begins in ethnography, by which I mean the descriptive account of the various peoples considered mainly in their relation to their geographical environment. Thus, from the beginning to the end of his work, the student of anthropology is reminded that he is trying to deal with the varieties of human life in the concrete. He must first make acquaintance with the peoples of the world in their unanalysed diversity, must next proceed to the separate consideration of the universal constituent aspects of their life, and then, finally, must return to a concrete study of these peoples in order to explain, as well as he can, from every abstract point of view at once how they have come to be what they are. If this theoretical path be pursued, I have little fear lest anthropology appear to the man who has really given his mind to it a thing of rags and tatters.

The second way in which the unity of anthropology may be made manifest is, as I have said, practical. The ideal university course in anthropology should aim directly and even primarily at producing the field-worker. I cannot go here into the question whether better work is done in the field by large expeditions or by small. For educational purposes, however, I would have every student imagine that he is about to proceed on an anthropological expedition by himself. Every part of his work will gain in actuality if he thinks of it as something likely to be of practical service hereafter; and, to judge from my own experience as a teacher, the presence in a class of even a few ardent spirits who are about to enter the field, or, better still, have already had field-experience and are equipping themselves for further efforts, proves infinitely inspiring alike to the class and to the teacher himself. Once the future campaigner realises that he must prepare himself so as to be able to collect and interpret any kind of evidence of anthropological value that he comes across, he is bound to acquire in a practical way, and, as it were, instinctively, a comprehensive grasp of the subject, such as cannot fail to reinforce the demand for correlation and unification that comes from the side of theory. . . .

The conclusion, then, of the whole matter is that, for practical and scientific reasons alike, our universities must endow schools of anthropology on a liberal scale, providing funds not only for the needs of teaching, but likewise for the needs of research. Money may be hard to get, but nevertheless it can be got. We must not hesitate, as organisers of education, to cultivate the predatory instincts. For the rest, it is simply a question of rousing public opinion in respect to a matter of truly national importance. If anything that I have said to-day can help in any way to improve the position of anthropology among university studies, I shall be satisfied that, trite as my subject may have seemed to be, I have not misused the great opportunity afforded to every holder of my present office.

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

LIVERPOOL.—Mr. C. Sydney Jones has given the University the sum of 8000*l.* for the endowment of the chair of classical archæology, in memory of his father, the late Mr. C. W. Jones, who was one of the founders of the chair in 1906.

LONDON.—The several faculties have elected their respective deans for the period 1916–18; among these are:—*Medicine*, Sir Bertrand E. Dawson, London Hospital Medical College; *Science*, Prof. Herbert Jackson, King's College; *Engineering*, Dr. H. C. H. Carpenter, Imperial College of Science and Technology; *Economics*, the Hon. W. Pember Reeves, London School of Economics.

OXFORD.—Much interest has been aroused in Oxford by the debate in the House of Commons on the second reading of the Rhodes Estate Bill. The Bill proposes to establish twelve scholarships of 300*l.* a year each in lieu of the fifteen scholarships of 250*l.* tenable by German students nominated by the Kaiser. The scheme in its present form contemplates the distribution of the twelve new scholarships among colonists of the British Empire, but it is felt in some quarters that it might be advantageous, and not out of accordance with Mr. Rhodes's intention, to extend the benefit to a wider sphere. The adoption of Lord H. Cecil's proposal to give the committee power to grant discretion to the trustees to make the substituted scholarships available for students whether within or without the British Empire has accordingly been received by many with approval. It remains to be seen what form the Bill will ultimately take in its passage through Parliament.

---

SIR DOUGLAS HAIG, Commander-in-Chief of the British Forces in France, has been elected rector of St. Andrews University, in succession to Lord Aberdeen.

ACCORDING to the *Nieuwe Courant*, the number of women students in the German universities during the last summer semester was 5460, or double the number of 1911. The women now represent 10·5 per cent. of matriculated students, as against 4·8 per cent. in 1911. Of the students actually present in the universities (*i.e.* outside the Army), the women now form one-third. The number of women medical students is now 1394, as against 582 in 1911. In this way the losses caused by the war will to some extent be repaired, for the first 600 German casualty lists contain 1500 names of medical men.

THE Institution scholarship of the North-East Coast Institution of Engineers and Shipbuilders for the present year has been awarded to E. V. Telfer. The council of the institution, believing that the time has arrived for making the subjects of the scholarship examination of the institution more comprehensive than hitherto, has decided that the syllabus of future examinations shall be:—(1) English; (2) English history and geography; (3) Latin, Greek, French, or German (one of the four); (4) extra mathematics; (5) and (6) either experimental science and mechanics, or any two of the following:—Chemistry, physics, mechanics.

A COMMITTEE was appointed at the Newcastle meeting of the British Association to report upon the method and substance of science teaching in secondary schools, with particular reference to the place of such instruction in general education. The following resolution was adopted by the committee at a meeting held on October 18:—"That in order to secure freedom of action for teachers of science in schools, and to prevent the instruction from becoming stereotyped, it is undesirable for any external authority to prescribe a detailed syllabus in science for use in schools, whether intended as the basis of examinations or otherwise."

IN his recent presidential address to the Institution of Automobile Engineers Mr. L. A. Legros dealt, among other topics, with the part science might with advantage take in the education of our governing classes. He spoke of the deplorable ignorance of technical and scientific matters among those on whom the responsibilities for running the war have fallen. Never, he said, in the history of engineering has the ignorance of science by the politicians, the military, and the other authorities been so openly displayed as in the early stages of the war, and never has it proved so costly in time, in life, and in substance. The views of teachers brought up on classical lines are, he maintained, devoid of that perspective which would enable them to realise that for the majority of their pupils the dead languages are useless except as a discipline or gymnastic which can be provided as efficiently in the course of work which is really useful to them. A knowledge of the classics is undoubtedly of value to men of the clerical, legal, literary, and even of the medical professions, but, Mr. Legros urged, how much greater would have been the value, in this war, of that small section which deals with politics had it been as well grounded in the sciences as in the dead languages?

MR. M. S. PEASE has sent us from Ruhleben a copy of the prospectus of work for the autumn term at the Ruhleben Camp School. It would be difficult to provide more convincing proof of the hope for the future which inspires our countrymen at Ruhleben and of the courage and initiative of these prisoners there than the arrangements they have made for study and self-improvement. The camp school is in charge of a businesslike general committee, which has discovered in the camp teachers of nearly every conceivable subject, means for arranging and equipping laboratories for practical work, for starting a good library, and for holding examinations in connection with the home examining authorities. The prospectus is able to print the proud boast that "in most subjects the tuition provided by the school ranges from that required by absolute beginners to that required by advanced university students." We can refer here only to some of the numerous departments, and mention may be made of those for biological sciences, mathematics and physics, chemistry, engineering, and nautical subjects. In zoology, for example, courses are being given in vertebrate embryology, and in the study of the Echinodermata; in botany the Gymnospermæ are being studied, with laboratory work; all branches of pure mathematics, including, for instance, infinitesimal calculus and differential equations, are being taught; lectures and laboratory work are available in all branches of chemistry; and every branch of engineering is catered for. No saner way of relieving the awful tedium of prison camp life could be found than the classes and circles for study which have been provided by the Ruhleben Camp Committee.

IN Scotland for some time it has been possible for young men to obtain engineering training by attending during the winter classes in the universities, and by getting works experience in the summer. This plan suits Scotland, where the university session is condensed and there is a long interval between the closing of the university and its reopening. In England the university session is distributed more evenly throughout the year, and Dr. Wertheimer, the dean of the faculty of engineering of the University of Bristol, has,

Digitized by Google

therefore, proposed a modified "sandwich" system of training. A student on leaving school will enter the university and will spend a session there, passing the intermediate examination for the B.Sc. degree in engineering at the end; if his record is good, and he is a promising student, he will be recommended to a firm which will allow him to enter its works for a period of fourteen months. This will enable the student to judge to what extent he is fitted for an engineering career, and will also enable the manufacturers to form an impression as to his suitability. He will then return to the university and continue his studies for a further period of two years, in some cases spending the long vacation in the works; after that he will return to the same works, if he has given satisfaction, for another period of fourteen months. A number of firms have already agreed to take part in the experiment, so that a satisfactory trial is assured. The "sandwich" scheme, besides providing an improved method of engineering training, will also, it is hoped, bring the important firms which are taking part in it into closer touch with the University, and thus lead to more co-operation in research and other matters.

## SOCIETIES AND ACADEMIES.

### MANCHESTER.

**Literary and Philosophical Society**, October 3.—Prof. S. J. Hickson, president, in the chair.—Prof. F. E. **Weiss**, Sir E. **Rutherford**, W. **Thomson**, and Dr. G. **Hickling**: The discussions at the Newcastle meeting of the British Association.

October 17.—Prof. S. J. Hickson, president, in the chair.—Prof. W. H. **Lang**: *Rhynia Gwynne-Vaughani*, Kidston and Lang, a new type of vascular cryptogam from the Old Red Sandstone of Rhynie, Aberdeenshire. The chert in which the plant occurs was discovered by Dr. Mackie, of Elgin, and the plant remains are being studied by Dr. R. Kidston and Prof. W. H. Lang, the results being published by the Royal Society of Edinburgh. Photographic slides showed the underground rhizomes attached to the peaty soil by rhizoids, the branched cylindrical aerial stems, which were leafless, and the large cylindrical sporangia. The internal structure is well preserved, so that our knowledge of this ancient land plant is very complete. Rhynia differs so much from other vascular cryptogams that a new class, the Psilophytales, has been founded to contain it.

### PARIS.

**Academy of Sciences**, October 9.—M. Camille Jordan in the chair.—P. **Puiseux**: The physical libration of the moon, studied on forty photographs obtained at the Paris Observatory between the years 1894 and 1909. The method of measurement and calculation employed is fully described, and the conclusion is drawn that the theory of the movement of the moon round its centre of gravity, established by considering the satellite as an indeformable body, does not correspond with the facts.—D. **Eydoux**: The transmission of strokes of a hydraulic ram in pipes with bifurcations.—F. **Roy**: The sound of distant cannonades. The complexity of the question. A description of observations made at Sceaux. Heavy cannonades can be heard at tube are as heterogeneous as those given by other bulbs, and give a relatively complex spectrum. Filtration through a non-selective screen, such as aluminium, may be made to give a roughly monochromatic beam. From a discussion of the action on a silver bromide emulsion, it is shown that a practically monochromatic radiation can be obtained by interposing a selective screen containing a substance (cadmium, antimony) with an atomic weight slightly higher than that of silver.—P. **Nicolardot**: The action of reagents upon French, Bohemian, and German glassware. Glassware for chemical purposes is now made by several firms in France. Some of these glasses have been submitted to the attack of various chemical reagents (water, solutions of hydrochloric acid, ammonia, ammonium chloride, sodium carbonate), comparative tests being carried out under the same conditions with Jena glass, two Bohemian and two Thuringian glasses. The French glasses proved to be equal to the best German glasses. Comparative tests were also carried out on the resistance of the glasses to sudden changes of temperature and to the action of water at temperatures up to 160° C. Complete analyses of the French, Jena, and Bohemian glasses used are given.—A. **Pictet**, L. **Ramseyer**, and O. **Kaiser**: Some hydrocarbons contained in coal. A soft Sarre coal was extracted on the large scale (five and a half tons) with benzene. From the extraction product (0·25 per cent. of the coal) seven unsaturated and seven saturated hydrocarbons were isolated. These have been compared with the hydrocarbons obtained by the distillation of coal at 450° C. in a vacuum, and it is shown that a part, at least, of the hydrocarbons of the vacuum tar exist as such in the coal. The extracted material proved to be optically active, although no fraction from the vacuum tar possessed this property. Hence it would appear that a temperature of 450° is sufficient to racemise the volatile active substances contained in coal. This furnishes a proof that the materials from which the coal has been formed have never been carried to that temperature.—R. **Masse** and H. **Leroux**: The estimation of phenol in crude tar phenols. The process suggested consists of a preliminary fractional distillation, followed by a determination of the melting point.—J. **Bougault**: The semicarbazones of α-ketonic acids. The α-iodocinnamic acids.—G. **Barthelat**: The structure of the floral pedicel of Mesembryanthemum.—M. **Mirande**: The cytological formation of anthocyanin in the living plant.—M. **Molliard**: The disengagement of oxygen arising from the reduction of nitrates by green plants.—Em. **Bourquelot**: Remarks on the rotatory powers of the α- and β-alcohol-*d*-glucosides and alcohol-*d*-galactosides.—J. **Legendre**: The destruction of mosquitoes by fish. It has been proved that the Chinese carp (*Carassius auratus*) flourishes when introduced into the rice plantations of Madagascar, devouring the larvæ of the mosquito in large numbers, thus helping to reduce malaria.—A. **Lumière**: The presence of the tetanus bacillus at the surface of projectiles buried in cicatrised wounds.

## DIARY OF SOCIETIES.

*THURSDAY*, NOVEMBER 2.

ROYAL SOCIETY, at 4.30.—Waves in an Elastic Plate: Prof. H. Lamb.—(1) Multiple Integrals; (2) The Order of Magnitude of the Coefficients of a Fourier Series: Prof. W. H. Young.—A Determination of the Heat of Vaporisation of Water at 100° C. and 1 Atmosphere Pressure in Terms of the Mean Calorie: T. C. Sutton.—The Mechanical Relations of the Energy of Magnetisation: G. H. Livens.

MATHEMATICAL SOCIETY, at 5.30.—Annual General Meeting.—Address of Retiring President: The Fourier Harmonic Analysis; its Practical Scope and its Limitations: Sir Joseph Larmor.—Multiple Integration by Parts and the Second Theorem of the Mean: Prof. W. H. Young.—Moving Axes and their Uses in the Differential Geometry of Euclidean Space: E. H. Neville.—Areas and Conformal Representation: J. Hodgkinson.

CHEMICAL SOCIETY, at 8.—Overvoltage Tables. Part IV. The Theories of Overvoltage and Passivity: E. Newbery.—Studies of the Carbonates. Part II. Hydrolysis of Sodium Carbonate and Bicarbonate, and the Ionisation Constants of Carbonic Acid: C. A. Seyler and P. V. Lloyd.—The Synthesis of Hydroxyquercetin: M. Nierenstein.—(1) The Reaction between Methyl Iodide and some Metallic Cyanides; (2) Some Reactions produced by Mercuric Iodide: E. G. J. Hartley.—The Dual Theory of Acid Catalysis. A Comparison of the Activities of Certain Strong Acids: H. M. Dawson and T. W. Crann.

EUGENICS EDUCATION SOCIETY, at 5.15.—Mental Differences in Children: C. Burt.

*FRIDAY*, NOVEMBER 3.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—Thomas Hawksley Lecture: The Gas Engineer of the Last Century: H. E. Jones.

*SATURDAY*, NOVEMBER 4.

GEOLOGISTS' ASSOCIATION, at 3.—Followed by Annual Conversazione.

*MONDAY*, NOVEMBER 6.

SOCIETY OF ENGINEERS, at 5.30.—Heating and Ventilating Private Dwelling-Houses: C. T. A. Hansen.

ARISTOTELIAN SOCIETY, at 8.—Presidential Address: The Problem of Recognition: Dr. H. Wildon Carr.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—The Great Passes of the Western and Central Alps: The President.

*TUESDAY*, NOVEMBER 7.

ZOOLOGICAL SOCIETY, at 5.30.—Two New Species of Cestodes belonging respectively to the Genera Linstowia and Cotugnia: Dr. F. E. Beddard.—Notes on the Development of the Starfishes *Asterias glacialis*, O.F.M., *Cribrella oculata* (Linck), Forbes, *Solaster endeca* (Retzius), Forbes, *Stichaster roseus* (O.F.M.), Sars: Dr. J. F. Gemmill.—Studies on the Anoplura and Mallophaga, being a Report upon a Collection from the Mammals and Birds in the Society's Gardens. II.: B. F. Cummings.—Notes on a Collection of Heterocera made by Mr. W. Feather in British East Africa, 1911–13: Lt.-Col. J. M. Fawcett.—The Structure and Function of the Mouth-parts of the Palæmonid Prawns: L. A. Borradaile.—Heude's Collection of Pigs, Sika, Serows, and Gorals in the Sikawei Museum, Shanghai: A. de C. Sowerby.—The Classification of the Tineinæ, a Subfamily of Moths of the Family Pyralidæ: Sir G. F. Hampson.

INSTITUTION OF CIVIL ENGINEERS, at 5.30.—Address by the President, Sir Maurice Fitzmaurice, and Presentation of Medals awarded by the Council.

MINERALOGICAL SOCIETY, at 5.30.—Humite: Prof. W. J. Lewis.—(1) The Combination of Twin Operations; (2) Modification of the Kohlrausch Method of Determining Refractive Indices: Dr. J. W. Evans.—The Basalts of Hare Island, West Greenland: A. Holmes.

RÖNTGEN SOCIETY, at 8.15.—Presidential Address; Capt. C. Thurstan Holland.

*WEDNESDAY*, NOVEMBER 8.

FARADAY SOCIETY, at 5.30–7 and 8.30–10.30.—General Discussion on Refractory Materials.—Introductory Address: Sir R. Hadfield.—The Texture of Refractories: Dr. J. W. Mellor.—The Application of Petrographic Methods to the Study of Refractory Materials: Prof. W. G. Fearnsides.—Silica as a Refractory Material: Cosmo Jones.—The Transmission of Heat through Materials Employed in Furnace Construction: Ezer Griffiths.

GEOLOGICAL SOCIETY, at 5.30.

*THURSDAY*, NOVEMBER 9.

ROYAL SOCIETY, at 4.30.—*Probable Papers*: Methods of Raising a Low Arterial Pressure: Prof. W. M. Bayliss.—Selective Permeability; the Absorption of Phenol and other Solutions by the Seeds of *Hordeum vulgare*: A. J. Brown and F. Tinker.—The Toxic Action of Dilute Pure Sodium Chloride Solutions on the Meningococcus: C. Shearer.—The *Kéir* of the Phagocyte in Cerebro-spinal Meningitis: C. Shearer and H. W. # SUCCESS !

If success in your experiment is dependent upon the Filter Paper, it may be commanded by the use of Whatman Filter Paper.

**For all general filter purposes use Nos. 1-5. There are at present Four Acid Extracted grades (practically ashless); two more, Nos. 43 and 44, are in preparation.**

## WHATMAN FILTER PAPER

**No. 1. Equivalent to C.S. & S. 595.**

**No. 2. Equivalent to C.S. & S. 597.**

**No. 3. Equivalent to C.S. & S. 598.**

**No. 4. Equivalent to C.S. & S. 604.**

**No. 5. Equivalent to C.S. & S. 602.**

**No. 30.** Hydrochloric acid treated. Low ash, close texture. For quantitative work. **Equivalent to DREVER-HOFF 207.**

**No. 40** A paper treated by both Hydrochloric and Hydrofluoric acids. Has less ash than No. 30. For very accurate quantitative work. Retains finest precipitates. **Equivalent to C.S. & S. 589.** (White Ribbon.)

**No. 41** Treated same as No. 40, but more open and filters more quickly. Not recommended for filtering very fine precipitates unless properly precipitated. **Equivalent to C.S. & S. 589.** (Black Ribbon.)

**No. 42.** A new grade, resembling Nos. 40 and 41 in chemical qualities, but differing in its physical properties, being much harder and extremely close in texture. Suitable for use in filter pumps. **Equivalent to C.S. & S. 589.** (Blue Ribbon.)

**Nos. 43, 44 and 50, also Folded Filters and Fat Extraction Thimbles, will be out shortly.**

# MACMILLAN & CO.'S NEW BOOKS.

## Discovery; or, The Spirit and Service of Science.

By **Professor R. A. GREGORY.** With 8 Plates. Crown 8vo. 5*s.* net.

*THE BRITISH TRADE REVIEW.*—"Professor Gregory has given us in 'Discovery' an ideal book for our elder boys and girls, and for adults who want to know something of the methods and results of science. With accurate and competent learning, and in a style many 'men of letters' would like to have, he tells the wondrous tale of scientific Discovery, linking it with the names of humble-souled but gloriously-minded men who have given their lives to, and often for, science."

PART IV. JUST PUBLISHED. COMPLETE IN 1 VOL. (Pts. I.–IV.) NEARLY READY.

## A Class-Book of Chemistry.

By **G. C. DONINGTON,** M.A., late Senior Chemistry Master, City of London School, Author of "Practical Exercises in Chemistry." Illustrated. Crown 8vo. Part I. 1*s.* 6*d.* Parts I. and II. 2*s.* 6*d.* Parts II. and III. 2*s.* 6*d.* Parts I.–III. 3*s.* 6*d.* Part IV. METALS. 2*s.* Complete in 1 Vol. Pts. I.–IV. 5*s.*

*NATURE.*—"The earlier parts have rendered useful service to the teaching of elementary chemistry, and the present volume is up to the level of those previously issued."

## A Laboratory Manual of Foods and Cookery.

By **EMMA B. MATTESON** and **ETHEL M. NEWLANDS.** Crown 8vo. 6*s.* 6*d.* net.

## A Manual of Practical Physics.

By **H. E. HADLEY,** B.Sc., A.R.C.Sc., Principal of the School of Science, Kidderminster. Illustrated. Globe 8vo. 3*s.*

*NATURE.*—"Mr. Hadley is the author of a number of excellent works on physics, and the present small volume gives further proof of his ability as a clear exponent of physical principles. The book is suitable for the upper classes at schools where practical physics forms, as it should do, part of the science course."

## A Text-Book of Practical Physics.

By **H. S. ALLEN,** M.A., D.Sc., Senior Lecturer in Physics, University of London, King's College, and **H. MOORE,** A.R.C.Sc., B.Sc., Lecturer in Physics, University of London, King's College. Extra crown 8vo. 8*s.* 6*d.* net. Also PART I. PROPERTIES OF MATTER. 3*s.* net. PARTS II., III., and IV. SOUND, LIGHT, AND HEAT. 3*s.* net. PARTS V. and VI. MAGNETISM AND ELECTRICITY. 3*s.* net.

*NATURE.*—"The book as a whole is a valuable addition to the list of text-books on practical physics, and the authors show an intimate acquaintance with the difficulties of both students and teachers which should make it very acceptable to both."

PART II. NOW READY.

## Practical Mathematics for Technical Students.

Part II. By **T. S. USHERWOOD,** B.Sc., Wh.Ex., A.M.I.Mech.E., and **C. J. A. TRIMBLE,** B.A. Crown 8vo. 7*s.* 6*d.*

*** Previously published: Part I. 3*s.* 6*d.*

*THE JOURNAL OF EDUCATION.*—"A great deal of useful material is placed before the readers of this book without cramping and without ever failing in interest."

# IMPROVED IMMERSION OIL

**For all Varieties of Oil Immersion Objectives.**

As the outcome of numerous experiments we have succeeded in producing an oil which is distinctly superior to any on the market.

Mr. E. M. Nelson and other experts give very favourable reports. Faults attributed to objectives can often be traced to the use of an unsuitable oil.

The new Oil is supplied in bottles at 9d., 1/4, & 4/- (post 3d. extra), also in bulk.

*Prepared in the Laboratories of*

**FLATTERS & GARNETT, Ltd.,**
**309 OXFORD ROAD (Opposite the University), MANCHESTER.**

# Dr. A. HUTCHINSON'S NEW UNIVERSAL GONIOMETER

**For the Examination of Small Crystals and Mineral Grains.**

This instrument can be used for any of the following purposes:—
As an Ordinary Goniometer for the Measurement of Angles.
As an Axial-angle Apparatus.
As a Kohlrausch Total-reflectometer.
For Determining Refractive Indices by the Prism Method.
For Experimental Work in Mineralogy.

*Descriptive Pamphlet on application to the Makers:*

**JAMES SWIFT & SON,**

# PATENT ELECTRICAL RESISTANCE FURNACES.

(Patent No. 10,415, 1914.)

**For Temperatures up to 1000°C. wound nickel chromium wire; above 1000°C. to 1300°C. wound platinum strip.**

Furnaces for the Laboratory built on our patented principle in all Types and Sizes:—

(1) **Vertical and Horizontal Tube Furnaces.**
Specially recommended for Annealing purposes.
(2) **Carius Explosion Furnaces.**
(3) **Multiple Tube Furnaces for the determination of Carbon in Steel.**
(4) **Crucible Furnaces.**
(5) **Muffle Furnaces.**

*ARRANGED FOR ALL VOLTAGES—D.C. or A.C.*

**ADVANTAGES.—Low Cost, Long Life, Low Current Consumption. Can easily be taken to pieces in a few minutes, allowing immediate renewals to be made by the user with repair parts we supply.**

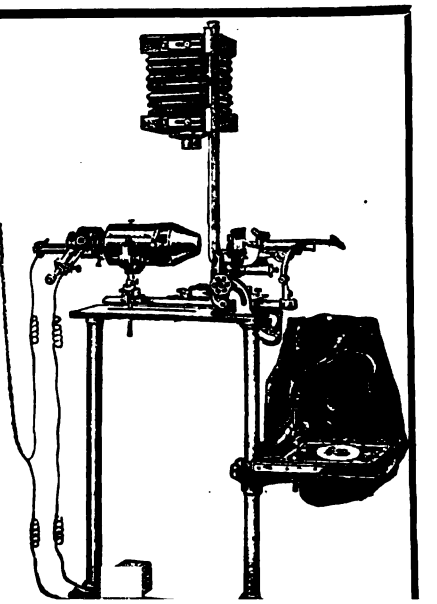
# Bausch and Lomb

## New Combined Drawing and Photomicrographic Apparatus.



Most complete instrument for low or high power photomicrography in horizontal or vertical position. The attachment for drawing is most conveniently placed, and can be raised or lowered to suit the convenience of the operator.

The apparatus can be used with the microscope either horizontally or vertically, and serves simultaneously as a projection outfit for lantern slides or micro-projection of transparent or opaque objects.

Dark-ground illumination is also rendered to the greatest perfection, so that this instrument can justly claim to be universal, and applicable for research work of any kind.

Price, complete, exclusive of microscope—

**£32 : 6 : 0**

*Demonstration of this instrument will gladly be given in our Demonstration Rooms by appointment.*

**Please write for particulars (Catalogue "Ca.1") post free.**

## SWINEY LECTURES on GEOLOGY, 1916.

UNDER THE DIRECTION OF THE TRUSTEES OF THE BRITISH MUSEUM.

A Course of Twelve Lectures on "The Mineral Resources of Europe" will be delivered by Dr. JOHN S. FLETT, F.R.S., at the ROYAL SOCIETY OF ARTS, 18 and 19 JOHN STREET, ADELPHI, W.C. (by permission of the Council of the Society).

The Lectures, which will be illustrated by Lantern Slides, will be given on Tuesdays, Thursdays, and Fridays, at 5 p.m., beginning Tuesday, November 14, and ending Friday, December 8. ADMISSION FREE.

British Museum (Natural History),
Cromwell Road, London, S.W.

## GRESHAM LECTURES.

The Gresham Lecturer on Astronomy, Mr. ARTHUR R. HINKS, M.A., F.R.A.S., will deliver a Course of Four Lectures on "THE EARTH AND THE UNIVERSE," on Tuesday, Wednesday, Thursday, and Friday, November 14, 15, 16, and 17, at 6 p.m., at Gresham College, Basinghall Street, E.C. Admission Free.

## CHEMICAL SOCIETY RESEARCH FUND.

A meeting of the Research Fund Committee will be held in December next. Applications for grants, to be made on forms which can be obtained from the ASSISTANT SECRETARY, Chemical Society, Burlington House, W., must be received on, or before, Friday, December 8, 1916.

All persons who received grants in December, 1915, or in December of any previous year, whose accounts have not been declared closed by the Council, are reminded that reports must be returned by Friday, December 1.

The Council wish to draw attention to the fact that the income arising from the donation of the Worshipful Company of Goldsmiths is to be more or less especially devoted to the encouragement of research in inorganic and metallurgical chemistry. Furthermore, that the income due to the sum accruing from the Perkin Memorial Fund is to be applied to investigations relating to problems connected with the coal-tar and allied industries.

## ASTLEY COOPER PRIZE.

The next Triennial Prize of Three Hundred Pounds, under the will of the late Sir Astley Cooper, Bart., will be awarded to the author of the best Essay or Treatise on "Gunshot Wounds of the Lungs and Pleura."

The competition is open to everyone except the staffs of Guy's and St. Thomas's Hospitals and their relations; but the essay must not be the production of two or more authors. Candidates are informed that their essays, written in English, must be sent to Guy's Hospital, addressed to the Physicians and Surgeons, on or before January 1, 1919. Each essay or treatise must be distinguished by a motto, and be accompanied by a sealed envelope containing the name and address of the writer; none of the envelopes will be opened except that which accompanies the successful treatise.

The Trustees will entertain the question of the publication of the successful essay in the "Guy's Hospital Reports." This will not, of itself, preclude the successful competitor from publishing his essay elsewhere upon obtaining permission.

For particulars regarding the other conditions to be complied with, application should be made to C. H. FAGGE, M.S., Guy's Hospital, London, S.E.

## COUNTY BOROUGH OF HUDDERSFIELD TECHNICAL COLLEGE.

Principal: J. F. HUDSON, M.A., B.Sc.

DEPARTMENT OF COAL-TAR COLOUR CHEMISTRY.

"BRITISH DYES" RESEARCH SCHOLARSHIPS.

The Governors invite applications for two Scholarships of the value of £75 each and tenable for one year in the first instance.

The object of these Scholarships is to encourage and afford greater facilities for research upon problems in connection with the Coal-Tar Colour Industry in Great Britain. The Research is to be carried out in the Department of Coal-Tar Colour Chemistry of the Technical College, Huddersfield.

Full particulars may be obtained on application.

T. THORP, Secretary.

## AGRA COLLEGE, AGRA, INDIA.

Applications are invited for the PROFESSORSHIP OF BIOLOGY at AGRA COLLEGE, UNITED PROVINCES, INDIA. Salary Rs. 500 per mensem (£400 per annum), with free quarters and Provident Fund benefits. Particulars may be obtained from Professor GREGG WILSON, M.A., D.Sc., Queen's University, Belfast.

## LABORATORY ASSISTANT WANTED

for LANCING COLLEGE. Some experience in a chemical laboratory desirable. Wages 25s. per week.—Apply at once to K. L. TREBLE, Lancing College, Shoreham-by-Sea.

## LURGAN URBAN DISTRICT.

WANTED, PRINCIPAL AND SECRETARY FOR TECHNICAL SCHOOL.

The Lurgan Technical Instruction Committee require the services of a PRINCIPAL and SECRETARY (to devote his whole time to the work of the School), possessing qualifications in Technology recognised by the Department of Agriculture and Technical Instruction, and having had experience of the working of Technical Schools. Salary £200 per annum.

Applications, stating age, &c., will be received by the undersigned not later than 12 o'clock noon on Friday, November 24, 1916.

Canvassing by or on behalf of candidates will be deemed a disqualification.

J. W. POLLOCK,
Acting Secretary.

Technical School, Lurgan,
October 24, 1916.

## AN ASSISTANT CHEMIST with experience in the analysis of minerals and the assay of ores is required temporarily in a public laboratory in London. Salary £150 to commence. Applicants must be ineligible for military service. Write, giving usual particulars, to "CHEMIST," c/o STREET'S, 30 Cornhill, E.C.

## FOR SALE.—OBSERVATORY & EQUATORIAL of the late DAVID G. SIMPSON, late F.R.A.S. Dome 11 ft. 6 in. inside diameter. Telescope 4½-in. Wray, 6 ft. f.l. with driving clock, circles divided on silver, Thorpe spectroscope, eyepieces, &c. For particulars apply by letter to Mrs. SIMPSON, "Rosefield," Widmore Road, Bromley, Kent.

GLEW'S SCINTILLOSCOPE
(PATENT)
SHOWS a magnificent display of scintillations, showers of sparks, direct from the mineral Pitchblende, Radium, Polonium, Uranium, Thorium, or any radio-active substance, even an Incandescent Gas Mantle contains sufficient Thorium to excite the very sensitive screen of the Scintilloscope, which is far more sensitive than the Spinthariscope. The Scintilloscope rivals the most delicate Electroscope as a detector of Alpha rays.

The eye sees an inexhaustible shower of stars of white light, giving a very realistic idea of the ceaseless activity of these marvellous substances which are producing the terrific bombardment causing this beautiful display.

GLEW'S SCINTILLOSCOPE, Superior Lens, with Extra-sensitive Radium and Pitchblende Screens, giving brilliant effects. Complete, 7/6, Post free, U.K. Foreign Postage extra, weight 2 ounces.

Pieces of Pitchblende mineral, ground flat and polished, with Sensitive Screen attached, for use in Scintilloscope or with any strong pocket magnifier, from 7/6 each, according to size.

F. HARRISON GLEW (PATENTEE), 156 Clapham Road, London, S.W.

ANALYTICAL REAGENTS
"A.R."

The B.D.H. Analytical Reagents are British Made and are guaranteed to conform strictly to the "A.R." specifications formulated by the Special Committee appointed by the Councils of the Institute of Chemistry and the Society of Public Analysts.

# THE "GALVANOSET" No. 1

A device for utilising the main supply of electricity, continuous or alternating, of any voltage, for the *immediate* production of low voltage currents from 0·5 to 100 volts such as are required for

**LABORATORY EXPERIMENTS.**

This apparatus has been largely employed by the medical profession for producing the currents that are required for passing through the human body, for which purpose accumulators and dry cells have been hitherto employed.

The apparatus comprises a vessel of water, two fixed electrodes, and two movable electrodes. The main current is connected through two lamp resistances to the movable electrodes, and the circuit of utilisation is connected to the two terminals shown at right and left of the vulcanite top of the vessel.

When the four electrodes are at right angles, *i.e.* at equal distances apart, the potential at the utilisation terminals is zero; when moved a degree from this position, a potential is at once obtained varying in intensity with the amount of displacement. The polarity of the supply can be readily reversed by moving the pointer in the opposite direction. The complete apparatus weighs 7 lb. only. The price of **£8 8 0** includes a moving coil milliamperemeter with shunt winding; if this is not required, the price is only **£6 6 0**

To summarise, the following advantages render the "GALVANOSET" superior to all other methods:—

Nothing to get out of order.
No expense for upkeep.
Always ready for use.
Does not require re-charging.
Nothing to wear out.
Costs less than one farthing per hour to run.
Safe under all circumstances.
Finest range of adjustment.
Any desired current.
Light and portable.

THURSDAY, NOVEMBER 9, 1916.

## THE EMPIRE AT THE CROSS-ROADS.

*Eclipse or Empire?* By Dr. H. B. Gray and S. Turner. Pp. x+316. (London: Nisbet and Co., Ltd., 1916.) Price 2*s.* net.

THIS book will serve the useful purpose of directing popular attention afresh to the important questions of education and scientific research in relation to national prosperity, on which so many eminent scientific men have given emphatic warnings. It is the joint production of a scholar and of a man of business, and although primarily addressed to the man in the street, deserves attention from everyone concerned with education or with commercial manufacture. Its principal aim is to show that Great Britain, which forty years ago was the workshop of the world, is so no longer. It supports this statement by an inquiry into the reason for this decadence and by useful statistics.

The book is divided into three parts. The first is concerned with the development of the main thesis of the book and an analysis of the causes of this falling off in British productiveness, and then with a discussion of the defects of British education in its several stages of primary, secondary, technical, and university rank. The second part of the book deals more particularly with industry in its relation to pure science and to the State, and the third part is a glossary, or detailed examination, of various trades and industries, with the object of supporting the contention that in the last twenty to forty years most of the new ideas, inventions, and developments have been given to the world by other countries than our own.

The second chapter, on "The Englishman at Home," contains a short but searching analysis of our national character, its love of sport and recreation, restiveness under discipline, and dislike of State organisation. The third chapter, on "The Slackening of Momentum," shows by telling figures and statistics how serious has become our competition with better organised or more hard-working nations. Fifty years ago Great Britain produced per annum, according to the authors, nearly 5 million tons of iron and 225,000 tons of steel. Germany produced barely 1 million tons of iron and 100,000 tons of steel. Yet in 1913 German production of both iron and steel had risen to 19 million tons of each, whilst English production had only increased to 10½ million tons of iron and 7½ million tons of steel.

We find the same deficiency in whichever direction we look. British production has increased at a far less rate than that in Germany or in the United States. As regards home-grown wheat it has fallen by 20 per cent. in the last thirty years in England, and increased in Germany by 50 per cent. Only 5 per cent. of the cultivated land of Great Britain is devoted to-day to wheat production. In the last thirty years the cost of raising coal to the pit's mouth has nearly doubled in England, but has slightly decreased in the United States. The value of the annual output per man in ten different trades reveals not a single case in which it is not much greater in the United States than in the United Kingdom.

In the third part of this book these facts and figures are extended, and it is shown how fatal in its results has been the cherished conviction of the manual labourer and trade-unions that restriction of output operates to the benefit of the working classes. The direct opposite is, in fact, the truth, that high wages and high rate of production go together. Tracing, then, the causes of these erroneous ideas in the minds of manual workers, and the neglect of science in its applications by the manufacturer, our authors find it primarily in our defective systems of primary, secondary, and university education. They sketch out in detail the reforms that are required, and with their main suggestions most scientific men will be in sympathy. Science, they say, should be the first wheel of the educational coach and not the fifth. For our primary and public-school education they demand a more rational and useful syllabus, and a reduction in the time spent over the grammar of dead languages. We think, however, that the authors do not lay sufficient stress on the necessity for ethical and civic training. The man in the street regards the Germans, as seen in the light of the present war, as a nation of moral decadents, to whom cold-blooded murder, lies, cruelty, and treaty-breaking are only the natural expression of character. He says, though very illogically, if this be the result of a widely diffused scientific education, then the less we have of it the better. On the other hand he sees that our inefficient systems of education have at any rate produced a nation of young heroes, and he draws the conclusion that they cannot be so bad after all. The point which needs pressing is that the German character is the result, not of an over-cultivation of science, but of a disastrous perversion and deficiency in moral and ethical training. We have nothing to fear from educational programmes which give predominance to science, provided only that they give the right position to character training as well.

The second part of this book deals with the relation of science to industry and to the State. The authors do not, however, sufficiently distinguish between pure and technical research. The former will always be chiefly conducted in the universities and technical colleges, and in public or private research laboratories. The technical research must be conducted by voluntary associations of the trades concerned. The authors have not given sufficient attention to the opinions of those who have practical experience in this side of the subject. What is required from the State is a proper support for the existing institutions. The authors call for State endowed and provided laboratories, but the real difficulty is to find the right men and not the apparatus.

One lamentable result of the war is the loss

Digitized by Google

to the country of many brilliant and promising members of the younger research workers, who cannot be quickly replaced.

The glossary contains a large amount of interesting information. Some sections are contributed by experts, but we think that in many cases British work is unduly depreciated or neglected. In the section on "Telephones" the name of David E. Hughes, the inventor of the microphone, is not even mentioned, nor that of Oliver Heaviside, whose mathematical work led to the invention of the loaded cable.

The section on "Wireless Telegraphy" is very inadequate as a sketch of the subject. The writer seems to think that the coherer is still used as a receiver, whereas it has long since been abandoned. Two out of three of the actually used modern detectors are British inventions. Marconi's work, all carried out in England, is not sufficiently appreciated.

British invention in connection with submarine cable work, almost entirely a British industry, is ignored. The initiative quality of British scientific research is not sufficiently acknowledged. Nevertheless there remains sufficient to justify the main contentions of the book. We have all to turn over a new leaf, to reform educational methods, to work much harder, play much less, and bring the scientific method to bear on everything, or else the eclipse the authors foresee most certainly awaits us in the post-war struggle for commercial empire. J. A. FLEMING.

## VINEGAR.

*Vinegar: its Manufacture and Examination.* By C. Ainsworth Mitchell. Pp. xvi+201. (London: Charles Griffin and Co., Ltd., 1916.) Price 8*s*. 6*d*. net.

THIS book seeks to fill an admitted void in the technology of an important fermentation industry. Works on the subject are to be met with in French and German literature, but their bearing on English procedure is only indirect, since the methods and conditions of acetification in this country are fundamentally different from those prevailing on the Continent.

Strictly speaking, the manufacture of vinegar—that is, the commercial preparation of a dilute acid from wine, capable of being used as a condiment or preservative, is not, and never has been, a British industry, since wine is not one of our native products. A similar, but by no means identical substance, was made in this country, even in very early times, by the souring of beer, and was known as "alegar"—a term practically now obsolete, or only to be met with in certain local glossaries. Formerly a clear distinction was drawn between the Continental and the native commodity. Thus Boorde's "Dyetary" (1542) speaks of "Soure and Tarte Thynges as Venegre and Aleger," and for many years the term vinegar was restricted to the imported variety derived from wine. So little was known in this country concerning the manufacture of this special article that the Royal Society, in one of the early volumes of its Transactions, published "The Way of making Vinegar in France: Communicated to the Publisher by an Ingenious Physician of that Nation, living at a Place where much of it is Made."

With us the manufacture of vinegar—using that term in its generic sense—still bears the impress of how it originated in this country—that is, from beer. Formerly the only useful way of disposing of sour beer, whether in the brewery or the household, was to turn it into vinegar. But as the demand for vinegar increased some more regular supply than "sick" or badly brewed beer was needed, and the manufacture was gradually placed upon a systematic and independent basis. Still this connection between the brewer and the vinegar maker long persisted. The fiscal authorities at least swept them into a common net—the fermented malt-product, no matter whether it was sweet or sour, coming within the purview of the gauger—although "Vinegar-Beer," as a Revenue Act of Charles II. termed the product, was let off with a lighter impost. "Vinegar-yards," as distinguished from the "common brew-houses," seem to have been first established in this country about the middle of the seventeenth century.

In the book under review Mr. Ainsworth Mitchell, who acts as chemist to the well-known firm of Messrs. Beaufoy and Co., one of the oldest and largest vinegar manufacturers in this country, has brought together a body of valuable information concerning the history of vinegar in general, its different varieties, and various modes of production, with special reference to English procedure; and this information he has presented in an interesting and eminently readable form. In his historical retrospect he begins his account at the period when vinegar received a certain amount of scientific attention from the early alchemists, and their immediate followers, the iatro-chemists, who speculated upon its nature and physiological action. It is interesting to note that certain of their crude theories still persist in old wives' fables, and in the practice of quacks. The author touches lightly upon the early theories of acetification, but of course he deals with the suppositions of Liebig and the far sounder views of Pasteur, Nägeli's mechanical theory, and the more modern Enzymic theories. This is followed by a description of the acetic bacteria, their various species, zooglæal condition, and involution forms, and the effect of light and oxygen upon them. These chapters are fully illustrated, showing the morphological changes of the bacteria due to age, and the character of the medium. They do not pretend to be exhaustive, as they are intended rather for the general reader than for the specialist, but so far as it goes the account is sound, and no important point is omitted. The chemical reactions in acetification are next dealt with, including the production of aldehyde, acetal, and the various esters which confer upon the different vinegars their characteristic aroma and other peculiarities. Next follows a description of acetic acid, its chemical and physical properties, and its

Digitized by Google

preparation from verdigris, from spirit vinegar, and from pyroligneous acid, and there is a short reference to a few of the processes which have been described (and patented) for the synthetic production of acetic acid by inorganic methods.

But perhaps the most interesting section of the book to the lay reader is the description of the modern methods of making vinegar from an infusion of malt or malt and grain, as practised in England, and it is here that the author's technical knowledge and experience give his work a special value. The processes are described in detail, and are well illustrated, showing the most approved forms of mash-tuns, mashing machines, sparges, refrigerators, fermenting tuns, acetifiers, sterilisers, etc. The remaining chapters deal with the chemical methods of examining vinegar, and with the characteristics of different vinegars.

The author as a chemist concerned with the manufacture of vinegar has naturally something to say on the relations of that substance to the Food and Drugs Acts, and on what is known as the malt vinegar question. At present both the law and the practice are admittedly in a somewhat chaotic condition. What is held to be legitimate trading in one county renders a dealer liable to a criminal prosecution in another. The Local Government Board has no power to fix legal definitions of food substances, but in response to the appeal of the Association of Vinegar Brewers it has suggested certain definitions. These definitions have not been universally accepted by public analysts, nor, when accepted, have they been regarded as obligatory by certain stipendiaries who are more concerned to dispense law than justice. The consequence is there is a considerable amount of confusion in administration, and malpractices tend to be perpetuated which might readily be put an end to by the exercise of a little common sense on the part of judicial authorities.

## INVARIANT THEORY.

*A Treatise on the Theory of Invariants.* By Prof. O. E. Glenn. Pp. x + 245. (London: Ginn and Co., 1915.) Price 10*s.* 6*d.* net.

LIKE many other branches of mathematics, the theory of invariants has gone through stages similar to those of gold-mining. We may reckon Gauss, Lagrange, and Eisenstein among the pioneers; Boole, Cayley, Sylvester, and Salmon found the first big nuggets; and Aronhold's symbolic method may be compared to the rocker which extracted gold-dust from alluvial deposits. Finally, the refractory problem of finding complete systems led Gordan to invent his transvectant formulæ, corresponding to the stamps and cyanide tanks now used in South Africa.

The present book illustrates very well the state of the subject at present. The author gives all the important methods, both for binary and ternary forms, including annihilators of sources, polar theory, Aronhold's symbolic method, and Gordan's series. Complete systems are given for binary forms up to the quintic inclusive, and for certain pairs of forms; tables are also given for two ternary quadratics, and for the ternary cubic. Gordan's theorem is proved with the help of Hilbert's theorem and a lemma by Jordan, which simplifies the analysis. In the ternary theory an account is given of Clebsch's translation (*Uebertragung*) principle; nothing is said, however, about connexes.

The main novelty of the work is the account of modular invariants, the invention of Prof. Dickson. This remarkable theory illustrates once more the striking difference there is between umbral and arithmetical analysis. Fundamental problems, such as finding a complete system, assume an entirely new aspect, and lead to quite different results. Whether this new theory will have wide applications is uncertain; but there is no doubt of its theoretical interest and of the new turn it has given to a somewhat stereotyped part of analysis.

In connection with Gordan's theorem and the use made of Hilbert's theorem we may add a few remarks. To us, at any rate, there is some vagueness both in the statement and the proof of Hilbert's theorem; fortunately, however, so much of it as is wanted for the proof of Gordan's theorem practically amounts to the fact that linear diophantine equations of a certain type must have solutions that form what Dedekind calls a finite modulus. Hilbert's theorem is that any definite set of polynomials forms the whole or part of what Kronecker calls a modulus $(F_1, F_2, \ldots F_m)$, *i.e.* the aggregate of all expressions

$$\sum_{1}^{m} G_s F_s$$

where $G_1, G_2, \ldots G_m$ are arbitrary polynomials. The difficulty we feel may be illustrated by taking the case of four homogeneous variables and considering those polynomials which, equated to zero, represent all surfaces of given "deficiency" $p$; do these all belong to a finite modulus of the Kronecker type? To speak, as Prof. Glenn does, of polynomials as "formed according to any definite laws" is so very indefinite as to make us fear some tacit and illegitimate assumption in the proof. Very likely our difficulty is owing to our stupidity, but there it is; of course there is no great trouble in showing that the theorem does apply in a large number of important cases.

The present work is in many ways similar to that of Messrs. Grace and Young; it is rather more analytical in character, though there are a fair number of articles on geometrical applications and interpretations. We sometimes wish for another Clebsch to appear and give geometrical embodiment to these immaterial formulæ. The trouble is that the simplest analytical concomitants do not, as a rule, correspond to the simplest geometrical derivatives. For instance, a binary quintic has four linear covariants; suppose we represent the quintic by five points on a conic, each of the linear covariants must give a point on the conic derivable by projective construction from the original five; but it is not by any means

Digitized by Google

obvious what these constructions should be. On the other hand, we can easily get covariant sets of points by construction, but it is then troublesome to find their analytical equivalents. The results for the cubic and quartic are so simple and elegant that one would like to have some development, if possible.

It should be noted that Prof. Glenn has given, as an appendix, forty-eight very good and instructive exercises; and we may add that, in spite of its conciseness, the book seems as easy to read as the subject will permit. G. B. M.

## THE GROWTH OF TELEPHONY.

*The Telephone and Telephone Exchanges: their Invention and Development.* By J. E. Kingsbury. Pp. x+558. (London: Longmans, Green and Co., 1915.) Price 12*s.* 6*d.* net.

THIS book covers most of the ground relating to telephony from its earliest stages to the present time. It may, indeed, be regarded as a "Short History" of telephony, and, as a matter of fact, the author's original intention was to write a history, but circumstances were not favourable to the project. However, the future historian will find in Mr. Kingsbury's volume much useful historical matter and many finger-posts indicating different avenues of development which merit much fuller treatment than has been possible in this work.

A marked and valuable feature of the book is the numerous extracts from circulars of early telephone companies and from unpublished reports of experts and of telephone conferences, held principally in the United States. Only a person very intimately connected with the industry from its infancy could have obtained this exclusive information and made such judicious selection of material. Telephone engineers interested in the growth and development of their instruments and systems will feel indebted to Mr. Kingsbury for the masterly way in which the subject is dealt with in the work under review. If ever "scissors and paste" can be justified, this is a case in point; for here one gets the views of inventors and pioneers in their own words, "hot from the anvil" as it were, and free from any form of distortion due to narration by a second party. The work is not of the text-book order; persons desiring technical details of the latest instruments and appliances should consult other treatises, but those who wish to study early telephonic devices and the way they developed into present-day models will find in the volume much that they require presented in a very readable form.

The book is conveniently divided into thirty-three chapters and two appendices, one of the latter giving telephone statistics of the world, and the other relating to the increased telephone rates in Great Britain. In the first six chapters—headed, respectively, i., Introductory; ii., The Spoken Word; iii., The Growth of an Idea; iv., The Undulating Current; v., The Solution of the Problem; and vi., Development and Demonstration—the author traces the early uses of the word "telephone" for speaking-trumpets and speaking-tubes, for instruments depending on the transmission of sound through rods of glass, wood, etc., as in the "enchanted lyre," to the electrical transmission and reproduction of musical sounds, and eventually of human speech, by currents of varying strengths.

Subsequent chapters relate how the beautiful scientific instrument patented by Alexander Graham Bell in 1876 was, by the prevision and business acuity of the inventor and his American associates, made the basis of a new branch of electrical industry of enormous benefit to the public, and in a few decades permeated all parts of the civilised world and utilised capital amounting to some 400 millions sterling. The headings of these chapters are as follows:—vii., The Production of a Commercial Instrument; viii., The Application to Commercial Uses; ix., The Telephone Exchange; x., The Battery or Variable Resistance Transmitter; xi., The Microphone; xii., Philipp Reis and his Work; xiii., Call Bells; xiv., The Telephone Switchboard; xv., The Organisation of the Industry in the United States; xvi., Competition, Consolidation, and Development; xvii., Introduction of the Telephone in Europe and Abroad; xviii., Public Apathy and Appreciation; xix., The Multiple Switchboard; xx., Outside or Line Construction; xxi., Ten Years' Progress; xxii., The Development of Dry-core Cable; xxiii., Early Exchange "Systems"; xxiv., Telephone Engineering on a Scientific Basis; xxv., The "Branching" System; xxvi., The Common Battery System; xxvii., Automatic and Semi-Automatic Switchboards; xxviii., Long-Distance Service; xxix., Instruments; xxx., Rates; xxxi., The Economics of the Telephone; xxxii., The Telephone and Governments; xxxiii., Conclusion.

Chap. xii., on Reis's work, should, chronologically, be near the beginning of the book, but it is put later because "its consideration is facilitated by the preceding chapters." On the question of priority the author maintains that Reis invented a musical telephone and not a talking telephone, and that "his work had no direct effect on the invention of the speaking telephone, for Bell fortunately went on entirely independent lines and without any reference to the prior work of Reis." Throughout the book the work of Bell and his colleagues is given especial prominence, sometimes to the detriment of others, such as Reis, Hughes, Gray, and Edison. In fact, the "pro-Bellism" of the author is a feature to which some exception might be taken. In a similar way, when dealing with long-distance service, Pupin's work is highly and deservedly appreciated, whilst that of O. Heaviside (who made the discovery that by increasing the inductance of lines their speaking qualities could be improved) is insufficiently recognised. These, however, are minor blemishes in an exceptionally valuable book. T. MATHER.

## OUR BOOKSHELF.

*Subtropical Vegetable-Gardening.* By P. H. Rolfs. Pp. xviii+309. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1916.) Price 6*s.* 6*d.* net.

THE Rural Science Series, under the able editorship of Prof. L. H. Bailey, enjoys a deserved reputation for the high standard of excellence reached by its constituent volumes, and the one before us is no exception in this respect. Those whose lot is cast in the hotter parts of the world ought to be grateful to Mr. Rolfs for his practical and sensible work on subtropical vegetable growing. The author is the director of the experimental station of Florida. In America the exploitation of the land is looked on as a proposition of chief importance, and much enterprise, brains, and money are devoted to the solution of the multifarious problems that confront the cultivator.

Although Mr. Rolfs's book is designed primarily to meet the needs of the Florida people, it will be found, none the less, of great use in other parts of the tropical and subtropical belts, and the suggestive way in which difficulties of all kinds are indicated and disposed of should render it good reading to the dwellers of temperate zones as well.

The chapter on irrigation is an example to the point, for the water-question is certain to turn up in one form or another in all gardens, wherever they may be situated. The present writer has seen something like the subterranean methods of irrigation there described applied with remarkable results, even in this country. The cultural notes respecting the different vegetables are good, and the hints as to suitable manures, as well as the accounts of the various pests likely to be encountered, will be useful. In fact, the author is able to draw on a wealth of experience and knowledge which is at his disposal as head of an important experimental station, and we have no hesitation in cordially recommending the book to all whom it may concern, and furthermore in congratulating the author on the skill with which he has discharged his part of the matter.

*Earliest Man.* By F. W. H. Migeod. Pp. xii+133. (London: Kegan Paul, Trench and Co., Ltd., 1916.) Price 3*s.* 6*d.* net.

THESE are the musings and observations of one who has had long experience of life among primitive men and wild animals. While resident in the Gold Coast Colony the author not only devoted himself with well-known success to the study of the native languages, but was also a keen and thoughtful observer of the various tribes and their environment. He is, therefore, well equipped by first-hand knowledge for making suggestions as to the manner in which the earliest men may have gradually acquired the various habits and manifestations of intellect which distinguished them from their ape-like ancestors.

Mr. Migeod assumes that "if a creature of some species low in the scale of evolution can perform certain acts tending to operate on inanimate nature, another creature no lower, such as Pre-man, cannot be denied the possession of the same capacity. Further, if there are natural occurrences which can cause lower species to act out of their usual habits, and evince undoubtedly new mental activities, the same potential capacity must also be allowed in the case of Pre-man." He then discusses in order the possible origin of man's primary instincts, the making of implements, the use of fire, the beginning of speech, and his special social organisation, with the dawn of religion. He concludes with an interesting observation that when an ordinary monkey dies in the forest, the rest of the troop simply leaves the corpse and abandons the place, at least for a time; while when an ape such as a chimpanzee dies, its companions drop the body into a hole in the ground if one can be found, and in any case cover it with a great heap of sticks and branches.

Some of Mr. Migeod's conceptions of the laws and causes of organic evolution will by no means commend themselves to those who are accustomed to approach the subject from a wider point of view, but the novelty of the circumstances in which his little book was written makes it stimulating and interesting. A. S. W.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### A Nomenclature for "Resistance Derivatives."

IT is evident from Mr. Bairstow's National Physical Laboratory papers that the notion of "resistance derivatives" is likely to play a permanent part in the experimental study of aeroplane motions, as well as in the theoretical rigid dynamics associated with them. It therefore becomes important to have a uniform nomenclature for these quantities which shall be independent of the choice of axes, and thus free from any possible ambiguity or source of difficulty.

The following names are used by Mr. Bairstow to distinguish the quantities depending on translation and rotation respectively:—

| *Translational.* | *Rotational.* |
|---|---|
| Longitudinal. | Rolling. |
| Normal. | Yawing. |
| Lateral. | Pitching. |

Now, it will be found that a possible word of four letters can be made by combining the first two letters of any one of these names with the first two of any other, and such words are not more objectionable than nine-tenths of the names that are introduced to cover new inventions. The nine resistance derivatives for the longitudinal oscillations will then be designated as follows:—

| | | |
|---|---|---|
| Lolo | Lono | Lopi. |
| Nolo | Nono | Nopi. |
| Pilo | Pino | Pipi. |

While the names of the lateral derivatives will be:—

| | | |
|---|---|---|
| Lala | Laro | Laya. |
| Rola | Roro | Roya. |
| Yala | Yaro | Yaya. |

Digitized by Google

In the symbolic notations hitherto used the force component is always written first and the component of motion producing it is written after it as a suffix. It is therefore important that the same convention should be followed in the proposed nomenclature. Thus "Lopi" will stand for the $X_r$ of my "Stability in Aviation," while "Pilo" stands for $N_w$. These words take no longer to write than $\log x$ or $\sin x$, and it would be easy to employ them in writing down formulæ, which would thereby gain much in clearness and suggestiveness. G. H. BRYAN.

### Plastic Flowing of Metals.

REGARDING the interesting research work published from time to time on the plastic flowing of metals under stress, might not these results have a bearing on the action of the fusion of wires by electric currents? For instance, it is well known to electrical engineers that erratic results are obtained by the use of the present formulæ for calculating the so-called "fusing" currents of wires.

At present, so far as the theory of electrical fuse wires is concerned, these theories deal merely with the generation of heat per unit length in the wire, and the loss of heat per unit length of the wire. Now, whatever the gain or loss of heat may be, that in itself is surely merely a cause increasing the plasticity of the wire, and thereby allowing the mechanical stresses acting on the wire to break it. Consequently, it would appear that any theory which omits all reference to the mechanical stresses set up by the heating is necessarily incomplete, and represents only a portion of the process.

At present, owing to lack of experimental data, it is impossible to say whether one can predict the fusing for any metal of given dimensions, but so far the results obtained seem more promising than by the older methods. W. H. F. MURDOCH.

Westerlea, Mill Hill, Middlesex, November 1.

### Optical Deterioration of the Atmosphere and Volcanic Eruptions.

IN NATURE of October 5 it is stated that the cause of the optical deterioration of the atmosphere in July and August "is for the time being still in doubt. Up to the present no reports of volcanic eruptions have come to hand from any part of the globe."

I wish to state that in July a strong outburst occurred of the Stromboli volcano, and that on July 4 there was an extraordinary eruption of fluid and incandescent lava to a great height, followed by a thick rain of lapilli and ashes. The emission of enormous columns of black cloud lasted many days.

October 30.

## *POSITION AND PROMISE OF BRITISH DYESTUFF MANUFACTURE.*

THE question is frequently asked: "What is being done to produce British dyes?" Broadly, it may be said, the problem is being dealt with as efficiently as could be expected under present conditions. The difficulties may be roughly classified as follows:—

(1) The raw materials necessary for dyestuff culty that the necessary raw materials are released by the Munitions and other Government Departments.

(2) There is an extraordinary shortage of adequately trained chemists. This shortage has been accentuated owing to the great demand for chemists in explosives works, the sending of chemists to the Front to study questions of gas poisons, etc., the recruiting for military service, and the failure of tribunals to appreciate that one clever chemist working at home may discover the means of saving thousands of our men and accounting for the destruction of thousands of the enemy.

(3) The problems to be solved by chemists are not only numerous, but many are exceedingly intricate and complex. The patents taken out by Germans in this country for many years past have been drawn up in an extraordinarily skilful manner by the help of our ablest lawyers, patent agents, and experts, so as to disguise in every conceivable way the method of arriving at the production of the patented article or its manufacture. This has been a scandal that has been allowed to gain force year by year. It is almost incredible that we should have allowed ourselves to be hoodwinked in this way, granting these great privileges to powerful German firms in order to restrain manufacture in this country.

(4) A serious difficulty will have to be faced in settling the question as to how to distribute amongst chemical manufacturers the many problems that await solution. It is most desirable to avoid overlapping of effort in research, etc., or quite unnecessary duplication of plant. Otherwise we shall have, say, one firm trying to solve too many problems and others, quite competent and suitable, making no efforts at all. These questions, it is proposed, shall be dealt with by some central authority, such as the recently formed Association of British Chemical Manufacturers, one of whose objects is to help manufacturers in this and many other desirable ways, *e.g.* to unite their efforts to fight the common foe rather than to compete with one another at home. Had such an association been in existence early in the war, these particular troubles would have been largely avoided, and much valuable time and money saved.

(5) The U.S.A. Government, although relatively a Free Trade one, has lately promised duties of more than 100 per cent. on dyestuffs and chemical products after the war so as to help America to build up what to all intents and purposes is for them, as it is for us, an infant industry. Our Government has so far resolutely refused any definite indication in that direction; and yet without heavy protective duties, the chemical industry of the finer products, including dyestuffs, cannot possibly be built up and firmly established in this country.

Digitized by Google

if not the sole, excuse that could be adduced for Government support of a very substantial character to one firm only rather than helping a relatively large number of smaller concerns, which many now believe would have produced more immediately satisfactory results.

(7) In spite of manifold difficulties much has been done by universities and technical institutions of the higher order to help industry. Professors, lecturers, and post-graduate students have vied with each other in endeavours to meet many demands made upon them, and their collaboration with manufacturers has led in many cases to extraordinarily gratifying results. If all the facts could be published it would be a most agreeable surprise to many, who have taken an altogether too gloomy view of the possibilities of this collaboration. Leeds University and the Manchester School of Technology have started new departments for chemical research for special objects, such as the study of problems in connection with the dyestuff industry. Remarkably fine and eminently useful work has been carried out also for the Army and Navy. A great deal more could have been done in that direction but for the aforesaid shortage of well-trained chemists, the relatively small number of whom are at last "coming into their own." Salaries that would have been thought preposterously large a few years ago are now gladly paid. It is to be hoped that this will tend to attract to the profession a large number of suitable and able men as well as women. It may indeed be said that unless this takes place there is not much hope for the establishment and maintenance on an adequate scale of the dyestuffs and allied industries; and not only must those who have to deal with the scientific and practical side of the industry be chemists, but what is equally important, the men who direct the administrative side of the business must also be well-trained chemists of business experience, or good business men with a chemical training. It is facts such as these that are appreciated far less than they deserve to be. But the war is teaching us many things, and as we have perhaps at last realised the importance of the work of the chemist in war-time, so it is just conceivable that the nation may in time come to realise that in peace-time also industrial and material progress is going to depend more than it ever did before on the successful work of the chemist.

A. R.

## *PRESERVATION OF NATURAL COLOUR IN PLANTS.*

SO long ago as 1908 Prof. J. W. H. Trail described in the *Kew Bulletin* a method which he had worked out for fixing the green colour in plants. By placing the plant for a shorter or longer period in a boiling solution of copper acetate dissolved in acetic acid, a combination of the copper salt with the chlorophyll was formed which rendered the colour permanent when the specimen was exposed to the light after drying or placed in a preservative solution such as alcohol.

The method deserves to be more widely known than it seems to be among those interested in preparing plant specimens for exhibition in museums or for lecture purposes. It is essentially a method the results from which gain by experience; different plants lend themselves to the treatment with different degrees of success, and require very different periods of treatment; the time for which it is necessary to keep the plant in the boiling solution varies from one minute to forty minutes, according to the action of the copper salt upon the plant. If the action is proceeding satisfactorily, a period of one to five minutes should suffice; the end of the operation is easily judged by the colour or by treating two different specimens for different periods; a specimen that by such comparison appears to require longer treatment can always be reimmersed to get the desired effect. Many plants, notably the leaves of evergreen shrubs, are more difficult and generally less satisfactory in the ultimate colour, probably owing to the presence of mucilaginous or decomposition products or tannins. These require long treatment varying from twenty to forty minutes; after the first immersion they turn yellowish, and then after a time the yellow gradually gives place to green, generally an olive-green. Other plants, notably Aucuba, fail entirely, as they pass from the yellow to a muddy-brown or black colour.

After treatment the plants should be washed (like photographic prints) in running water for about two hours. They are then dried under as light pressure as is compatible with keeping the plants from twisting, or, after shaking off as much water as possible, may be dried in hot sand. In many cases the plants are rendered so flaccid by boiling that sand-drying is difficult or impossible. Plants that have required long boiling not infrequently revert to a bad colour when sand-dried.

Young parts of plants green better than old; better results may be expected from "spring" leaves than from "autumn" leaves.

A stock solution is made by saturating commercial strong acetic acid with powdered copper acetate. For treatment, dilute the stock solution with water in the proportion of three or four parts of water to one of stock solution. The solution is heated in a non-metallic vessel, glass beakers being probably the most suitable, and wooden, not metal, forceps should be used for manipulating the specimens.

This method has been used at the Natural History Museum for some time past in the preparation of plants for exhibition purposes, and good results have been obtained with cryptogams as well as flowering plants; ferns especially give satisfactory results, and, as Prof. Trail has noted, fresh green Algæ can be successfully treated. Proceeding out of these investigations, experiments have been made with the object of preserving the natural colour of seaweeds or of intro-

Digitized by Google

ducing a colour that is natural and permanent. The exhibition of Algæ in the Botanical Gallery, which has been recently rearranged, shows an appreciable success for the red Algæ and some satisfactory results for the brown Algæ. It is proposed to present an account of these experiments shortly before one of the scientific societies.

A. B. RENDLE.

## DR. J. O. BACKLUND.

ASTRONOMERS will hear with regret of the death of Dr. Backlund at Pulkova on August 29. He was a native of Sweden, having been born at Langhem, in Wermland, on April 28, 1846. He studied mathematics and astronomy at the University of Upsala, and in 1873 went to Stockholm Observatory as assistant to Prof. Gylden, whose new methods of perturbations he studied with enthusiasm. After a brief return to Upsala in 1875, he left Sweden for Russia, where he remained permanently. He was at Dorpat Observatory for three years, and in 1879 went to Pulkova as assistant to Dr. Otto Struve. On Prof. Bredichin's death in 1895 he was appointed director of the Observatory, retaining this post until his death.

Dr. Backlund is best known for his immense researches on the motion of Encke's comet, for which he received the gold medal of the Royal Astronomical Society in 1909. Encke had detected the acceleration in the comet's mean motion, which he ascribed to the action of a resisting medium. After his death in 1865 von Asten took up the research, adopting some of Gylden's methods. He was unable to represent the comet's motion by any constant value of the acceleration, and died at Pulkova in 1878 without solving the problem completely. Backlund took up the matter, receiving grants from M. E. Nobel and the Petrograd Academy of Sciences for assistance in computing the perturbations, which were redetermined from 1819 to 1891, and afterwards to 1911.

Backlund found clear evidence that sudden changes in the amount of acceleration took place in the years 1858, 1868, and 1895. He later found evidence of a fourth change about 1905; after this the acceleration had only one quarter of its value before 1858. He also studied the changes in brightness of the comet (it is generally brighter before than after perihelion), and made the tentative suggestion that its particles are flat and oriented parallel to a particular plane, so that when seen edgewise they reflect little light.

A valuable by-product was the determination of the mass of Mercury, the value being 1/9,700,000 of the sun. This mass cannot be found except by Odessa, and Feodosia, in the Crimea. He took part in the Russo-Swedish determination of an arc of the meridian, visiting Spitsbergen for this purpose. A valuable new method of determining the flexure of transit-circles was introduced at Pulkova under his auspices. In conjunction with Dr. Hough he formed a list of stars to be used as fundamentals in astrographical reductions, and arranged that the "Star Corrections" for several hundreds of them should be printed at Pulkova.

The British observers who visited Russia for the eclipse of August, 1914, remember with gratitude his kind help in the difficulties which arose from the outbreak of war.

## NOTES.

WE notice with much regret the announcement, in the *Times* of November 6, that Prof. H. H. W. Pearson, Harry Bolus professor of botany, South African College, Cape Town, died on November 3, at Mount Royal Hospital, Wynberg, at forty-six years of age.

THE many friends of Major T. Edgeworth David, professor of geology in the University of Sydney, will be delighted to learn that he has recovered from the effects of serious injuries received while conducting mining operations in northern France, and hopes shortly to rejoin his regiment.

IN answer to a question by Mr. Montague Barlow in the House of Commons on October 26, suggesting the adoption of the metric system of weights and measures, the Prime Minister stated that he was aware that the proposal to adopt the metric system had a certain measure of support, but that it was difficult to say how far this was general. He understood that the attention of Lord Balfour of Burleigh's committee had already been directed to the subject. This reply will probably not be regarded as encouraging by those who are of opinion that the immediate obligatory adoption of the metric system is urgently necessary in order that we may be fully prepared, when the war is over, to cope with competition in foreign trade. Though the metric system has been legal for all purposes of internal and export trade for nearly twenty years, very little advantage has so far been taken of it by the trading community generally; while the large body of retailers are still completely ignorant of the nomenclature and equivalents of the system.

EMERITUS PROFESSOR JOHN FERGUSON, who last year resigned the Regius chair of chemistry in the University of Glasgow, died, after a very brief illness, on November 3. Prof. Ferguson was in his eightieth year, and had held the chair since 1874. His connection with the University had been continuous, as student, assistant, and member of the Senate, for well over sixty years. Among his pupils or assistants were Prof. J. M. Thomson, Sir William Ramsay, Sir J. J. Dobbie, Prof. G. Henderson, Prof. W. Lang, Prof. Carrick Anderson, Prof. M. A. Parker, Dr. A. W. Stewart, and other distinguished chemists. He had made many contributions to the history of chemistry, to biblio-

Digitized by Google

books and MSS. in the Hunterian Library, on the catalogue of which he was engaged at the time of his death. On many occasions he was sent to represent the university at centenary and other academic celebrations at home and on the Continent. His fine presence and courtly manner made him an acceptable delegate on such occasions. He had accumulated a vast collection of medieval books and manuscripts dealing with alchemy, natural magic, "secrets," and "origins." It is to be hoped that the collection will be kept together for the benefit of students of scientific history.

THE leading article in *Engineering* for November 3 is devoted to a discussion on the status of the engineer. The divorce of the engineer from public affairs, and the minor place he occupies in popular estimation, are causing disquietude on the other side of the Atlantic, where a case has occurred recently of a lawyer having been appointed to the post of county engineer because it was held that the post must be filled by a politician. The actual engineering work has therefore to be done by deputy. This is characteristic of our own national services, where it has been common to appoint clerks as heads of departments, even when these are concerned with highly technical matters. The official view is that expert knowledge is unnecessary in such cases, as trained assistants can be secured to do the work, whilst the nominal chief signs the inevitable forms. As Lord Sydenham puts it, the results of such a system are that the man who knows all about some subject has to refer to, and be overruled by, someone who knows nothing whatever about it. The working of the system as exemplified during the recent times of stress has been more instructive than edifying.

WE record with much regret the death on November 5, in his forty-ninth year, of Prof. H. M. Waynforth, professor of engineering, King's College, University of London.

PROF. G. CAREY FOSTER, a past president of the Institution of Electrical Engineers, has been elected by the council an honorary member of the institution.

THE opening of the next annual meetings of the Institution of Naval Architects has been fixed for Wednesday, March 28, 1917.

DR. D. F. LINCOLN, a former secretary of the American Social Science Association, died recently in Boston at the age of seventy-five. He was the author of "School and Industrial Hygiene," "Electro-Therapeutics," "Hygienic Physiology," and "Sanity of Mind."

WE regret to note that *Engineering* for November 3 records the death of Dr. C. A. Harrison at the age of sixty-eight. Dr. Harrison was for many years engineer-in-chief to the North-Eastern Railway; the structures which remain as monuments to his skill are principally bridges. He was for a time a member of the council of the Institution of Civil Engineers, and received the degree of D.Sc. at Newcastle in 1906, as a tribute of honour to his work in connection with the King Edward Bridge.

THE death on October 29 of Prof. O. V. Muller is announced. Prof. Muller was professor of history and political economy at Elphinstone College, Bombay. A *Times* correspondent writes that during the plague in Bombay he laboured hard to persuade the plague-stricken to allow the

THE death is announced, in his seventy-first year, of Mr. V. G. Bogue, a leading American engineer. He was a member of a commission appointed by President Harrison to investigate the methods for improving the navigation of the Columbia River, and acted as consulting engineer for the Government of New Zealand on the proposed railway across South Island. He prepared the plan and report for Greater Seattle and for the harbour of Tacoma. While employed from 1880 to 1886 as an assistant engineer in the construction of the Northern Pacific Railway, Mr. Bogue discovered the Stampede Pass in the Cascade Mountains. From 1886 to 1891 he was chief engineer of the Union Pacific.

WE regret to learn of the death of Lance-Corpl. J. W. Hart, who, having volunteered in the early days of the war, was killed on September 15, while taking part in the first wave of an attack against the enemy trenches. Mr. J. Hart received his early training at University College, Reading, and showed the greatest promise as a student. He obtained the diploma in horticulture at Reading, and afterwards the B.Sc. (war) degree of London University. At the beginning of the war he held the post of horticultural assistant at Bedford College, London, and was in charge of the botany garden, the successful development of which was largely due to his skill and energy. Mr. Hart was no militarist; hating the wastefulness of war, he abandoned the constructive work he had at heart for that greater cause for which he believed his country to be fighting. His death will be keenly felt by the many friends to whom his manly, enthusiastic, and cheerful outlook on life had endeared him, while scientific horticulture has lost one of its most promising adherents.

A QUOTATION in the *Morning Post* from the *Gazette de Hollande* emphasises the use made in Germany of geological advice in trench warfare, and Prof. Salomon, of Heidelberg, is said to have urged the formation of a special organisation of geologists in connection with the Army. It is probably no secret that excellent use has been made by the British military authorities of our own Geological Survey staff, members of which have been of technical assistance in fields as wide apart as the deeply dissected strata of Gallipoli and the undulating Cretaceous expanses of the Paris-Brussels basin. The geologist has been found of service in military mining as well as in questions of water supply, and the memoir recently issued by the Geological Survey on "Sources of Temporary Water Supply in the South of England and Neighbouring Parts of the Continent" (see NATURE, vol. xcv., p. 244) was drawn up specially to meet the needs of camps.

A LECTURE was delivered at the Royal Society of Medicine on October 31 by Dr. Sherman, of Pittsburg, on the method of sterilising wounds introduced by Dr. Carrel, the well-known American surgeon. The method consists in opening up the wound so far as necessary to reach every part of it, and rubber tubes are passed into all the recesses, and are kept in place by gauze packing. An antiseptic solution is then allowed to flow from a container, and by means of the tubes flushes out every part of the wound. This is done every two hours, and the wound is re-dressed every day. The effect is very striking, and the wound is rendered completely sterile in a few days. The antiseptic solution employed by Dr. Carrel is Dakins's

Digitized by Google

by this method of treatment the healing of wounds is greatly accelerated.

DR. C. D. WALCOTT, secretary of the Smithsonian Institution, and Mrs. Walcott have just returned to Washington, D.C., after several months' field work on the Continental Divide, which forms the boundary line between Alberta and British Columbia south of the Canadian Pacific Railway, studying the Cambrian rocks. Mrs. Walcott visited Glacier, British Columbia, where she measured the position of two large glaciers, and determined that the front ice foot, in each case, had retreated at the rate of 100 ft. a year during the past two years. Steel plates were placed on the ice on the present surveyed boundary lines. The plates will be buried beneath the winter snows, but, since their positions are relatively low as to altitude, the snow will be melted off next summer, and their locations then will indicate the amount of forward flow of ice during the year. Mrs. Walcott's studies show that the ice has been steadily retreating during the past six years, and her measurements agree with observations made in Alaska. During the field work a large number of photographs were taken, including a dozen or more panoramic views, exposures being made on continuous films 8 ft. in length.

LIEUT. JOHN HANDYSIDE, who fell in one of the recent advances on the Somme, at the age of thirty-five, was a distinguished graduate of Edinburgh and Oxford, and since 1912 had been lecturer in philosophy in the University of Liverpool. At Edinburgh he carried off all the honours open to students of philosophy, and at Oxford, after taking a first in Greats, he was elected a fellow of St. John's College. On the completion of his Oxford course he returned to Edinburgh, and acted for three years as assistant to Prof. Pringle-Pattison. After his appointment to Liverpool, the long illness of Prof. Mair threw upon him the chief responsibility for the work of the philosophical department. It was a severe test, and Mr. Handyside proved himself a successful teacher and a most helpful colleague. In 1915 he was granted leave of absence for military service, and obtained a commission in the 16th Batt. King's Liverpool Regiment. He had been between three and four months at the front, and was mortally wounded while rallying his men during an attack. His engrossment in teaching work during the last years prevented him from writing much, but he had completed a translation of two of Kant's smaller treatises, which he intended to equip with a critical introduction, and he had also in view some independent work in ethics. It is hoped, therefore, that some specimen of his work may yet be published.

QUICKLY after Ehrlich and Metchnikoff, his fellow Jews, has passed Prof. Albert Neisser, of Breslau, whose name will ever be associated with theirs in the history of the scientific advance against venereal disease. He was only twenty-four when, in 1879, he identified the gonococcus, a markedly characteristic form of diplococcus which is the cause of gonorrhœa. He devoted all his later years to the study of venereal disease, contributing largely to the biochemical tests for the identification of syphilitic infection, and being the founder, fourteen years ago, of the German society which corresponds to our National Council for Combating Venereal Diseases, founded in London last year. Though the discovery of the gonococcus has not led, as yet, to the construction of any direct chemical remedy, such as salvarsan in the case of syphilis, or to the production of an antitoxin, as in the cases of diphtheria and tetanus, Neisser's discovery has nevertheless been of incalculable value in the treatment, the identification, and, in our own times, the prophylaxis of the disease. Thanks to him, the gonorrhœal nature of *ophthalmia neonatorum* has been demonstrated, and the dependence of many cases of rheumatism or arthritis upon the same organism; while gynæcology tells us that at least one-half of all the cases where a major abdominal operation is required in women are due to gonorrhœal infection, which is, in fact, the great steriliser of femininity, and a leading enemy of the birth-rate everywhere. Thanks also to Neisser, the treatment of the disease has been vastly improved, the introduction of protargol being due to him, and his warnings and the microscopic resources which we owe to him enable us to know that the disease is still present in many cases where it would otherwise have been ignored.

AT a time when it is strongly urged that more capital must be employed in food production, any method that will enable the farmer to calculate the risk of his crops being destroyed by unfavourable weather conditions deserves careful study. In the July issue of the *Geographical Review* (New York) Messrs. W. G. Reed and H. R. Tolley show how the risk for a crop which is in a condition to be damaged by frost between any two dates in spring and autumn may be computed if sufficient observations for that district are available. Using the well-known method of mean squares, "standard deviation" figures are calculated for 569 stations in the United States. These constants are a measure of the departure from the average dates of the last killing frost of spring and the first killing frost of autumn. Naturally these standard deviations are lowest for the central areas and highest for maritime States like Florida and California. If a crop is in a condition to be damaged on the average date of the last killing frost in spring, the risk is 50 per cent. In the case of a station with a standard deviation of 14·4 the risk falls to 10 per cent. nineteen days later than the average date. By combining the risks in spring and autumn the total risk may be computed for a crop which is exposed to both dangers. The risk of loss which may be profitably carried naturally varies with the crop and the economic conditions. Given the necessary data, the authors believe that risks from weather conditions other than frost may be computed in this way.

IN the Proceedings of the American Philosophical Society (vol. lv., No. 3) Dr. Raymond Pearl describes some interesting experiments on the effect of continued administration of alcohol to the domestic fowl. Comparing the control group and the alcoholised group, he finds that there is no evidence that specific germinal changes have been induced by the alcohol treatment, at least in those germ-cells which produced zygotes, and that the germ-cells which produced zygotes were not in any respect deleteriously affected. Although the results are apparently in contradiction to those of some observers with mammals, the writer believes that the contradiction is more apparent than real. The discrepancy, he argues, is fundamentally due to a difference in the resistance of the germ-cells to alcohol.

DR. CARL HANSEN-OSTENFELD has published (Mem. Acad. Roy. Copenhagen, Sect. Sc., 8 ser., t. ii., No. 2, 1916) an account of the Protozoa found in the samples of plankton taken in Danish seas from 1898 to 1901. Some of these organisms, *e.g.* ciliates of the genus Tintinnopsis, are indigenous, but the majority, *e.g.* the two recorded species of Heliozoa, several species of Radiolaria and of Tintinnoid ciliates, appear to have been carried by currents from the North Sea into the Skager Rak or the Cattegat, but it is evident that most of them do not penetrate far, as they meet with water of low salinity from the Baltic, which is inimical

Digitized by Google

to them. Noctiluca—a globular Cystoflagellate, about 1 mm. in diameter, and well known for its phosphorescence—is occasionally present in enormous quantities in Limfjord, but cannot maintain itself inside the Skager Rak; it disappears each winter and is reintroduced in the following autumn by the "Jutland current." A few planktonic organisms are carried into the Danish area by the outgoing current from the Baltic. One of these—*Ebria tripartita*, referred to a new order Pyritoflagellata, near the Silicoflagellata—is found to be capable of living under wide variations of salinity (4 per mille to 25 per mille). A short account is given of the occurrence of Vampyrella (parasitic in the diatom, *Chaetoceras boreale*) and of Hyalosaccus (parasitic in Ceratium), both organisms of uncertain affinities. A list is appended of the phytoplankton and protozoa recorded from Danish waters.

SEVERAL articles dealing with different aspects of the geography of New York occupy the September number of the *Geographical Review* (vol. ii., No. 3). Mr. Ellsworth Huntington, writing on the water barriers of New York City, shows the important part that ferries and bridges play in the economy of the city, and the inevitable tendency towards crowding that arises from the island site. This results on one hand in "sky-scrapers" and high rents, and on the other in weakened health and nervous strain. Another article, by Mr. E. P. Goodrich, on some problems incident to the growth of New York City, is particularly valuable on account of the number of maps reproduced. Although these are necessarily much reduced, and in cases a little difficult to decipher, they illustrate many important considerations in town planning and municipal organisation which are essentially questions within the province of the geographer. Some of these maps incorporate useful suggestions for other towns.

THE recent formation of a conference of representatives of electric power supply companies to consider the best methods of linking up generating stations in the Greater London area, and the formation of a National Power Supply Joint Committee covering a still wider area, both point to a greater uniformity in orders and rules for the regulation of electric supply in the near future. It is to the interest of neither consumer nor supply company that a piece of apparatus which is pronounced dangerous or inefficient on one side of the street should be deemed adequate on the other side. That the same desire for greater uniformity in the rules for the regulation of electric supply is felt at the present time in America is shown by the recent issue by the Bureau of Standards of a circular of 260 pages dealing with the most important of the factors which determine the safety and efficiency of electric supply. It has been drawn up after conference with the supply companies and others concerned, contains rules and regulations suitable for companies under either State or municipal control, and gives specifications for the approval of the various types of electricity meters.

THE appendix to the annual report of the Board of Regents of the Smithsonian Institution for the year ending June 30, 1915, as usual, consists of a selection of miscellaneous memoirs of interest to all engaged in the promotion of knowledge. The articles for the most part are those of the year 1915. Many are translations into English of foreign contributions to science, and among these may be mentioned the following:—A review of astronomy for the year 1913, by M. P. Puiseux, of the Paris Observatory; the earthquake in the Marsica, Central Italy, by M. Ernesto Mancini, secretary of the Royal Academy of the Lincei; Atlantis, by M. Pierre Termier, director of the service of the Geologic Chart of France; construction of insect nests, by Prof. Y. Sjostedt, of the Royal Museum of Natural History, Stockholm; excavations at Tell-El-Amarna, Egypt, in 1913–14, Herr Ludwig Borchardt; and vaccines, by Prof. L. Roger, of the Paris University. The original contributions to the report include:—Evidences of primitive life, by Dr. C. D. Walcott, secretary to the Smithsonian Institution; olden-time knowledge of Hippocampus, by Dr. C. R. Eastman, of the American Museum of Natural History; progress in the reclamation of arid lands in the Western United States, by Mr. J. B. Beadle, of the U.S. Reclamation Service. The appendix, as is customary, is illustrated by a profusion of beautiful plates.

THE recent issue of the *Central*—the organ of the Old Students' Association of the City and Guilds (Engineering) College, South Kensington—is virtually a special number, in which some of Prof. Armstrong's old students have sought to put on record their impressions of the work of the Chemical Department of the college during the period from 1884 to 1914. The most remarkable feature of the record is perhaps the great variety of the subjects in which work of real value was done in a department which was always small in numbers, but for that very reason received an intensive cultivation which would have been impossible in a larger school or department. The writers include Prof. Pope, Mr. W. M. Heller, Prof. Compton, Dr. Lowry, Prof. Lapworth, Sir Henry Miers, Prof. Wynne, and Dr. Eyre, and Prof. Armstrong himself has added some "Personal Notes on the Origin and Development of the Chemical School at the Central." The chemical subjects touched upon in the record will be familiar enough to those who have followed the developments of chemical science during the past thirty years, but an even wider circle will welcome Mr. Heller's account of the "Reform in Education" with which Prof. Armstrong's name will always be associated. Sir Henry Miers has given an account of the school of crystallography at the Central, probably the only school in which the subject was taught regularly to all matriculated chemical students, and Dr. Eyre describes the biological investigations which became an important feature of the work of the department from 1900 onwards. The periodical contains an excellent photograph of Prof. Armstrong on holiday in 1909, and a list of careers of the students who passed through the chemical laboratory.

MR. C. BAKER, 244 High Holborn, London, has issued his October list of second-hand scientific apparatus. The list contains the usual large assortment of instruments, and all are guaranteed to be in perfect working order before being sent out. In view of the comparative scarcity of new apparatus owing to the demands of the war on manufacturers, this catalogue deserves the careful attention of science lecturers and others. The 1500 pieces of apparatus are for sale or, with some exceptions, for hire. The catalogue deals with microscopes and microscopic apparatus, surveying and drawing instruments, telescopes and accessories, spectroscopes, and a great variety of other physical apparatus.

MESSRS. H. SOTHERAN AND CO. (Strand and Piccadilly) have just issued the sixth and last part of their catalogue—"Bibliotheca Reuteriana" of modern standard works on mathematics, astronomy, physics, chemistry, engineering, crystallography, and meteorology, forming the final supplement to the "Bibliotheca Chemico-Mathematica." Messrs. Sotheran announce that after the war they will publish a library illustrated edition on fine paper of the "Bibliotheca Chemico-Mathematica" complete. It will contain

Digitized by Google

about 125 full-page plates and an analytical subject-index.

MESSRS. J. WHELDON AND CO., 38 Great Queen Street, W.C., have just published No. 76 of the new series of their catalogue. It deals with the journals and transactions of many scientific societies, and with English and foreign literary and scientific periodicals. There are also addenda giving particulars of remainders of books relating to natural history. The catalogue should be of interest and service to many students of science.

MR. F. EDWARDS, High Street, Marylebone, has recently circulated a very interesting illustrated catalogue of autograph letters, manuscripts, and historical documents. A section of the catalogue is composed of documents relating to the United States, Canada, and the West Indies.

THE two following volumes are in preparation, among others, for appearance in the "University of Chicago Science Series" (*Cambridge University Press*):—"A Factorial Theory of Evolution," by W. L. Tower, and "Chemical Signs of Life," by S. Tashiro.

## OUR ASTRONOMICAL COLUMN.

THE RADIAL VELOCITY OF $\beta$ URSÆ MAJORIS.—From observations of the radial velocity made at Potsdam some years ago it was concluded by Ludendorff that $\beta$ Ursæ Majoris was a spectroscopic binary with a period of 27·16 days and total range of 15½ km./sec. Subsequent observations made at the Lick Observatory, however, gave a range of velocity no greater than that to be expected in the determinations for a constant-velocity star of type A. Further interest in the question was aroused last year by Guthnick and Prager's observations of the star with a photo-electric photometer, from which a variation through 0·02 mag. in a period of 0·3122 day was deduced; the Potsdam radial velocity values were thought to be consistent with this period. A further investigation of the radial velocity, with special reference to short-period changes, has since been undertaken at Mt. Hamilton (Lick Observatory Bulletin No. 284). Thirty-six plates were taken on three nights during February, 1916, but, as in the case of the earlier photographs, these do not appear to indicate a variation through any appreciable or dependable range of velocities. Prof. Campbell hopes that someone with less observing opportunity and more opportunity for computation will make a further effort to discover a periodicity of very small amplitude. The plates are available for loan to any experienced measurer of spectrograms who may have a plan for remeasuring them.

RADIAL MOTION IN SUN-SPOTS.—Mr. Evershed has recently reported on some further investigations of the radial motion in sun-spots discovered by him in 1909 (Kodaikanal Observatory Bulletin 51). Improved results have been obtained by the use of instruments which reduced the times of exposure, and by working only under the best conditions as to definition of the spot image. It now appears that the radial motion displacement may be very unequal at equal distances from the umbra, and the two spots investigated showed larger displacements on the limb side than on the side towards the centre. There is usually an acceleration of velocity from the umbra to the outer limits of the penumbra, and then a sudden fall to zero, or to a lesser speed which diminishes to zero at some distance outside the spot. The radial movement may amount to as much as 4 km./sec. at one edge of the penumbra for lines of intensity 0 and 1 in large spots. The diminution of the indicated velocity with increased intensity, which was found by St. John, and attributed by him to differences of effective level, is confirmed by the new measures. In opposition to St. John, however, no difference was found for enhanced lines of iron as compared with the arc lines of like intensity. Mr. Evershed further concludes that while movements at right angles to the radial motion may occur in the penumbræ, rotational movement is not a constant feature.

WOLF-RAYET BANDS IN THE NUCLEI OF NEBULÆ.—In continuation of the work of Wright, the nuclei of three additional planetary nebulæ have been found by G. F. Paddock to give the Wolf-Rayet type of spectrum (Lick Observatory Bulletin, No. 284). The nucleus of N.G.C. 6826 shows a fairly bright band at 4686, and a fainter band at 4657, which is not given in Campbell's list of Wolf-Rayet lines. In N.G.C. 418, the band 4686 is faintly seen in the nucleus, while that at 4650 is fairly bright. Four bright bands were found in the nucleus of N.G.C. 40, namely:—

| Wave-length | | Width | | Intensity |
|---|---|---|---|---|
| 4862·2 | ... | 14 A. | ... | Faint. |
| 4788·3 | ... | 13 A. | ... | Faint. |
| 4687·4 | ... | 15 A. | ... | Fairly strong. |
| 4652·1 | ... | 22 A. | ... | Very strong. |

The band at 4652 is strongest near its violet edge, and seems to shade off towards the red. That at 4862 corresponds to $H_\beta$.

BARNARD'S HIGH PROPER-MOTION STAR.—Some interesting details relating to the discovery of the star with the largest known proper motion have been given by Prof. Barnard (*Popular Astronomy*, vol. xlvii., p. 504). The star was shown on plates taken in 1894, 1904, 1907, and 1916, and the images were so far apart as to seem to represent different objects, which might be new or variable stars. It was found, however, that all the images were in a straight line, and that the different photographs could be reconciled by supposing the images to have been made by a star with an annual proper motion of about 10″, in a direction almost exactly north. At the epoch 1916·423 the R.A. of the star was 17h. 53m. 43·60s., and the declination +4° 27′ 48″; it was 9·1s. following, and 51″ north of B.D.+4° 3560. The star is situated in the northern part of Ophiuchus, and is of about the 10th visual magnitude. The movement may easily be detected in the course of a few months, and photographs and charts are given for the benefit of those desiring to observe the star.

Mr. Adams has found that the type of spectrum is M*b*, and that the star is approaching the earth with a velocity of 91 km./sec. The relative intensities of certain spectral lines suggest a parallax of 0·2″, and it would follow from this that the star's real velocity in space is 260 km./sec.

A CATALOGUE OF METEORITES.—An illustrated handbook and descriptive catalogue of the meteorite collections in the United States National Museum, prepared by Dr. G. P. Merrill, has recently been published by the Government Printing Office, Washington. Though the handbook is intended primarily for the general public, it is so arranged as to provide also for the needs of the student and investigator. At the beginning of the present year the collection included 329 falls and finds, and an equal number of thin sections for microscopic study. There is a brief introduction, giving an interesting account of the characteristics of meteorites, and of the system of classification, following in the main that proposed by Brezina. In a large number of cases the results of analyses are given.

## MEMORIAL TO THE LATE SIR WILLIAM RAMSAY.

ON Tuesday, October 31, a public meeting was held at University College, London, to consider the steps to be taken to raise a memorial to the late Sir William Ramsay. The assembly included the Ministers of Belgium, Roumania, Serbia, Chile, China, a representative of the American Embassy, and various officials and members of scientific and academic bodies, many of whom took part in the proceedings.

The Rt. Hon. Lord Rayleigh presided, and, in the course of his introductory speech, made brief references to his work with Sir William Ramsay. We heard, he said, a great deal of the research which was needed in connection with industry, but there seemed to be no thought of the difficulty of getting the right kind of people to do it. Among every six people who were able to understand, form intelligible opinions, and explain scientific matters, there was probably not one who had the gift of scientific initiative. This Sir William Ramsay had to an extraordinary degree. Lord Rayleigh paid a tribute to his thoroughness of method and his indifference to criticism which did not rest on cogent argument. Ramsay's discovery of helium he described as one of the most romantic pages of science, and his further discovery that helium appeared during the breakdown of radium was most important. Sir William's gifts were not only scientific; he was a master of several languages, and this faculty placed him in touch with the scientific genius of the world; combined with his extraordinary experimental skill and rapidity, it went a long way to explain his success. In conclusion, Lord Rayleigh spoke of Sir William's unusual power of influencing people, as the result of which many things had been done since the war began that but for him would not have been done at all.

The following was the main resolution of the meeting:—"That steps be taken to raise a substantial fund as a memorial to Prof. Sir William Ramsay, K.C.B., F.R.S., such fund to be utilised for the purposes of promoting chemical teaching and research under a scheme to be approved hereafter by the subscribers."

The resolution was moved by the Rt. Hon. J. A. Pease, Postmaster-General, formerly President of the Board of Education. He laid stress on the importance of discoveries such as those of Sir William Ramsay, because they widened the horizon of all educated people, irrespective of country or of race; they enforced an essential unity of knowledge among civilised people, just as we were struggling for a similar unity of standard in conduct among the civilised States. One of the lessons of the war has been that we have learnt as a State to respect and be guided by scientific method and scientific men to a degree which nothing but a great necessity could have achieved. The work of Ramsay illustrates not only the necessary co-operation of sciences, but the necessary co-operation of nations. Was it therefore too much to ask that his memorial should be an international as well as a national one? A magnificent response has been made to an appeal for funds for the memorial to a great figure in the field of war, Lord Kitchener; cannot a similar response be made to an appeal for the memorial to a great figure in the field of science? To a people who could raise five mill[illegible]

of the University of Brussels) paid a graceful tribute to the memory of Ramsay, recalling a visit he paid to Brussels and the part he played in connection with the foundation by Solvay of the Institut International de Chimie; Ramsay did not merely belong to his own country; he belonged to humanity. Mr. W. H. Buckler, representing the American Ambassador, recorded the veneration in which Ramsay and his work were held in the United States.

In moving "That this meeting resolve itself into a General Committee for the purpose of raising the fund for the memorial to Prof. Sir William Ramsay," Sir Hugh Bell, Bart., referred to a suggestion made to him by Ramsay some time ago as to the possibility of distilling small seams of coal *in situ*. Probably no person other than Ramsay would have been able to persuade him that the experiment was at all possible, but, like others, he fell under the glamour of an entrancing personality, and arrangements were made for trying the experiment under extremely favourable conditions. These were nearly complete on the outbreak of war; the place was ready, and, if there were anyone found bold enough to pursue Sir William's suggestion, he would gladly put the preparations at the disposal of such person.

Prof. J. Norman Collie, the chairman of Convocation of the University of London and vice-chairman of the University College Committee (Sir Edward Busk), the president of the Chemical Society (Dr. Alexander Scott), Sir William A. Tilden, Dr. Morris Travers, Sir Joseph Larmor, and Prof. E. C. C. Baly also spoke.

The following were appointed an Executive Committee to make such arrangements as they deem desirable for furthering the memorial:—The Rt. Hon. Lord Rayleigh, the Rt. Hon. Lord Parmoor, Sir Hugh Bell, Bart., the Rt. Hon. Sir John Brunner, Bart., Sir Ralph C. Forster, Bart., Sir Charles Bedford, Sir G. T. Beilby, Sir James Dobbie, Sir Robert Hadfield, Sir Alexander Kennedy, Sir William Tilden, the President of the Royal Society, the President of the Chemical Society, the President of the British Science Guild, the President of the Society of Chemical Industry, Prof. Baly, Mr. Chaston Chapman, Prof. J. Norman Collie (hon. treasurer), Prof. F. G. Donnan, Mr. Alex. Duckham, Dr. T. Gregory Foster, Prof. F. Francis, Mr. Gathorne-Young, Mr. J. Gretton, Dr. R. Messel, Dr. Robert Mond, Dr. H. F. Parshall, Dr. Walter Seton, Dr. Samuel Smiles (hon. secretary), Lieut.-Col. Smithells, Dr. Morris Travers, and Prof. James Walker.

The proceedings terminated with a vote of thanks to Lord Rayleigh for presiding, moved by the Vice-Chancellor of the University of London (Sir Alfred Pearce Gould, K.C.V.O.), and seconded by Prof. F. G. Donnan, Sir William Ramsay's successor in the chair of general chemistry at University College, London.

After the meeting, Prof. J. Norman Collie delivered a memorial lecture on "The Scientific Work of Sir William Ramsay."

## THE SWISS SOCIETY OF NATURAL SCIENCES.

Digitized by Google

of Zernez and Tarasp on a ninety-nine years' lease by the Société Helvétique and the Ligue Suisse pour la Protection de la Nature, backed by the Federal Government itself. This has been set apart for the beasts and the birds and the plants to live in, there to breed and to struggle for existence in their own untrammelled way.

There is no other place in the world corresponding to this. The Yellowstone Park is open to the tripper, and the wilds still unexplored in Brazil and elsewhere, even when free from savage man, may at any moment be exploited by the rapacious European or American. But the creatures of the National Park of Switzerland are protected against the lord of creation by a charter, which, it is to be hoped, will never be treated as a mere scrap of paper. Picnickers even are forbidden, and it was only by special permission that the members of the Société Helvétique were supplied with excellent refreshment in a flowery pasturage within the precincts.

As you pass along the solitary paths you have to check the impulse to cull the many-coloured flowers that carpet the borders, and even spring up between the stones at your feet. This is one of the first rules of the park, and brings home to the visitor the fact that the park is no more for the collector than it is for the tourist.

It was in the earliest dewy morning of a beautiful August day that some two hundred members of the society started up the Gorge of the Clemgia. By ten o'clock they had reached a rocky ridge, the Alp Minger, dominating a flowery mead, untouched by the scythe. Here Prof. Schröder, one of the originators of the movement to which the park owes its origin, addressed the members in German. By midday the party had reached a magnificent height, the Col de Sur Il Fass, at the boundary of the park. Here they rested on the short velvety grass; it was too high for the luxuriance of vegetation which had marked the lower slopes. In front the ground fell sharply down into a ravine, on the other side of which a line of snowy peaks stood up clear against the sky. On this grand spot another of the originators, Prof. Paul Sarasin, of Basel, addressed the assembly in French, welcoming the society to the park, and characterising the aims of its institutors. He stated that the project is being entertained of founding a second park of the same kind in French Switzerland.

When he had finished, before the party left the park, it was characteristic of such Swiss functions that one of the many beautiful Swiss airs should be sung in chorus. The words were particularly appropriate, "Salut, glaciers sublimes."

This expedition took place on the last of the three days (August 7–9) devoted to the meeting. On the first day a lecture was given by Prof. Edouard Fischer, of Berne, on "The Notion of Species in Fungi," and by Dr. Briner, of Geneva, giving an account of the experiments carried out by himself and others on "The Rôle of Pressure in Chemical Phenomena."

The Schaefli prize was awarded to Prof. Gogel, of Fribourg, for a valuable memoir on "The Radioactivity and Electricity of the Atmosphere," and we may note, as perhaps the most interesting event of the meeting from a scientific point of view, the presentation by the veteran Zürich geologist, Prof. Heim, of the volume of memoirs of the society concerning the Rhone Glacier. The observations chronicled in this volume cover a period of forty years; they have for a long time been carried on under the direction of Col. Held, supported financially by the Alpine Club; the task of digesting the results has been ably effected by Prof. Mercanton, of Lausanne.

A large number of interesting communications were made in the sections of mathematics, physics, geophysics and meteorology, chemistry, geology and mineralogy. For a list of these we must, for want of space, refer our readers to the *Enseignement Mathématique*, where also abstracts of many of the papers will be found.

GRACE CHISHOLM YOUNG.

## *ANTHROPOLOGY AT THE BRITISH ASSOCIATION.*

PROF. RIDGEWAY, in a paper on "The Origin of the Actor," pointed out that an examination of Greek drama and its descendants in Europe, as also of non-European drama, led him to the conclusion that tragedy originated in the honouring or commemoration of the dead. Pantomimic dances representing events in the life of the dead were like funeral games—a means of keeping the dead in remembrance. The wearing of masks was a concomitant of such mimetic dances. Cases were quoted from many parts in which the masks represented the spirit in whose honour the ceremony was held. In some instances, as in Manipur, a living member of the community is regarded as the actual residence of the spirit of the departed until his final send-off to spirit-land, and dresses in the clothes of the deceased and takes his place at the family table until the last rites are performed. In ancient Rome the dead man was personated by an actor dressed to represent him, who copied his peculiarities and was accompanied by masked attendants to represent his ancestors. It is probable that these were regarded as the temporary receptacles of the spirits of the deceased and his ancestors. If in Greek time the actor was still regarded as the temporary abode of the hero's spirit Solon's anger against Thespis is explained.

Prof. Keith, in a paper entitled "Is the British Facial Form Changing?" described some interesting facts derived from a comparison of a series of ancient and modern complete skulls. He finds that the malar bone is becoming tilted as a result of a gradual atrophy from disuse of the zygomatic processes of the temporal and maxillary bones—a natural result of the change in dietetics which has occurred since the early years of the Christian era, cooked food and soft cereals replacing tough meats and imperfectly ground corns. Besides the obvious maxillary shrinkage in a lateral direction, bone has been laid down so as to increase the vertical dimensions of the jaws and also around the orifice of the nares. This deposit Prof. Keith regards as inexplicable on the mechanical theory as if due merely to disuse of the jaws, but thinks it to involve some change in the mechanism of bone production under the influence of the internal secretions of the ductless glands, hazarding the suggestion that it may be in some way associated with the increased prevalence of adenoids. Associated with the dietetic changes, it is interesting to note that in early British skulls, while the teeth were much worn and dental abscesses and pyorrhœa were common, ordinary dental caries was unknown.

In the discussion Miss Freire-Marreco pointed out that these changes in the incidence of dental disease could be observed occurring within a single generation among the Pueblo Indians.

Mr. W. G. Collingwood, in a paper on "Early Christian Monuments in Northumbria," traces the history of the Anglian crosses from finely ornamented forms with well-drawn saints and angels with elaborate plaits and leaf scrolls by a gradual debasement of figure drawing, simplification of interlaced patterns, and the conversion of scroll-work into dragonesque

Digitized by Google

ornament. All stages were shown, from early Anglian, in some respects resembling early Welsh, through the best Anglian period of native art and the decadent pre-Danish period, to the full Viking-age Scandinavian, which, however, received its fullest development beyond the boundaries of Northumbria.

Dr. Rivers presented a communication on "The Cultivation of Taro." In Melanesia and Polynesia taro is cultivated by means of irrigation, which is used for this purpose only. Perry has shown that irrigation has a distribution which corresponds closely with that of megalithic monuments, sun-cult, and other objects and customs which seem to have been carried over the earth by one migration or a connected series of migrations. The exclusive use of irrigation for the cultivation of taro in Oceania suggests that it also belongs to the group. This is confirmed by the distribution of the plant, which, when its tropical habit is taken into account, corresponds in general with that of other elements of the megalithic complex. An exception to this general correspondence occurs in the New Hebrides, where taro is absent or unimportant in a large part of the island of Malekula, although this island possesses a highly developed megalithic culture. Other evidence shows that the megalithic culture reached Melanesia in two chief waves, an earlier associated with mummification of the dead, and a later with interment of the dead in the extended position. The distribution of the cultivation of taro by irrigation in southern Melanesia points to its carriage by the earlier of these two migrations.

In "Personal Experience as an Element in Folk-tales" Miss Freire-Marreco pointed out that the striking resemblances between the dreams of children and those of adults of low mentality on one hand, and the myths of uncivilised peoples on the other, are to be explained, not by a semi-mystical analogy between the childhood of individuals and that of the race, but by supposing that very many folk-tales are founded on reported dreams, day-dreams, and trance experiences.

A study of "The Organisations of Witches in Great Britain" by Miss M. Murray showed that the witches practised a definite religion, with chief festivals, or sabbaths, at Candlemas, Roodmas, Lammas, and Hallowmas. The chief of the witches, called by Christian writers "The Devil," was regarded as a god incarnate in a man, or, when disguised in the skin of an animal, as incarnate in that animal. The ritual of admission into the society comprised the renunciation of any previous religion, dedication of body and soul to the god of the witches, vows of absolute obedience, baptism and the giving of a new name, and finally the signing of a contract or marking on the body, possibly by tattooing.

In papers on "A Summer and Winter among the Natives of Arctic Siberia" and on "The Physical Type of the Northern Tungus" Miss Czaplicka gave a descriptive account of the country and the native manners, customs, and types. Generally she showed that the Tungus in the north approach in type the Palæo-Siberians, and in the south the Mongols.

Mr. and Mrs. Scoresby Routledge described some of the results of their expedition to Easter Island, in the course of which they mapped and excavated the region of the terraces and of the images, and collected all that was still known of the old native culture. Little is now known by the natives with regard to the statues, though the last was overthrown so recently as 1830. The various features of the statues were, however, traced to customs of which knowledge remains. The life of the island appears to have turned on the finding of the first [illegible] were ten clans on the island perpetually at war, and cannibalism was rife. A special sanctity attached to the Miru clan, who alone had an Ariki, or chief, who was an authority on the tablets in an as yet unknown script found on the island, and who presided when these were read. It is not certain that these are very old, for white men who came in ships were regarded as gods, and ceremonies in their honour could be traced back for three generations.

In discussing the relations between "Magic and Religion," Dr. Jevons emphasised the importance of distinguishing from the earliest times between practices thought to be beneficial and of a religious character and those thought to be harmful and universally reprobated of a magical kind. Contrary to the views of Dr. Marett, he maintained there never had been or ever could be a magico-religious period or any practices which could be described as both magical and religious.

## AN IMPERIAL DEPARTMENT OF MINERALS AND METALS.

PROF. HENRY LOUIS described in NATURE of October 5 (p. 91) the need for the organisation of the mineral and metal resources and industries of the Empire. We reprint below the memorandum which has been sent to Sir William S. M'Cormick, administrative chairman of the Advisory Council for Scientific and Industrial Research, by the leading technical societies concerned with the subject. The proposal for the establishment of a central Department of Minerals and Metals has also been communicated to the Dominion Governments.

On behalf and by authority of the councils of the following institutions:—The Iron and Steel Institute (incorporated by royal charter as representing the iron and steel industries); the Institute of Metals (incorporated as representing the users and manufacturers of non-ferrous metals and alloys); the Institution of Mining Engineers (incorporated by royal charter as representing coal and iron ore mining and allied industries); and the Institution of Mining and Metallurgy (incorporated by royal charter as representing the mining of minerals other than coal and iron ores and the production of metals other than iron and steel); We, the undersigned, have the honour to submit the following considerations and recommendations in the hope that, through the intervention of the committee of the Privy Council for Scientific and Industrial Research, measures may be taken to provide the necessary machinery for the protection and advancement of the economic welfare of the mineral and metal industries of the Empire.

The absence of effective co-ordination of the organisations of these vital industries has been demonstrated and brought into prominence by the war, in many directions. The grave results to the national interests are generally admitted.

There are highly organised geological surveys and departments of mines in nearly all foreign countries, and their influence in the development of mineral resources is a factor of the first importance. There are similar well-organised departments in some of the British Dominions, but there is no connecting link or central "clearing-house" in the metropolis of the Empire to co-ordinate information on its mineral resources, to stimulate their development, and to safeguard Imperial interests.

Digitized by Google

present war, the Foreign Office, the Admiralty, the War Office, and the Ministry of Munitions, have all been concerned with the collection of information bearing on the sources of supply of minerals and the production of metals. There does not appear, however, to have been any serious attempt to co-ordinate and render available even such information as has been collected by these departments, and it is certain that there have been considerable overlapping and duplication of effort with corresponding waste and confusion.

It is, we submit, obvious that the overlapping and confusion will be seriously increased if the various technical committees appointed by the Advisory Council attempt to collect the information which is essential to enable the beneficent object of the committee of the Privy Council to be attained, in its wider aspects, in regard to the mineral and metal industries.

We respectfully urge this view upon the serious attention of the Advisory Council, as already there are evidences of increasing overlapping and consequent waste of time and energy, which we believe it is one of the main purposes of the committee of the Privy Council to eliminate so far as possible.

In the opinion of the institutions represented by us the organisation of a central Department of Minerals and Metals is imperatively necessary in the public interest, and the work of organisation, which will necessarily take much time to complete, should be commenced at the earliest possible moment.

It cannot be doubted that if a properly organised and efficiently conducted Department of Minerals and Metals had been in existence, much valuable time, many lives, and vast sums of money would have been saved to the nation in the conduct of the present war, and much of the cost and inconvenience to British industries depending largely for their raw materials on mineral products would have been saved, with corresponding advantages to the prosecution of the war and to many industries.

A Department of Minerals and Metals should not only be in intimate relationship with the Geological Surveys and Mines Departments of the Dominions, but also with the organisations representing the different branches of the mining and metallurgical industries, whose co-operation in the work of the department should form a vital part of its machinery.

The Geological Surveys of Great Britain and Ireland and the Museum of Practical Geology should also form an integral part of the department.

The functions of the department should be active and constructive. All overlapping by other Home Government departments, and also by the institutions representing the industries, should be absolutely prevented.

The duties of a Department of Minerals and Metals would include :—

(1) Arrangements for expediting the completion of mineral surveys of the United Kingdom and of the Crown Colonies and other British possessions.

(2) The systematic collection and co-ordination of information bearing on the occurrence, uses, and economic value of minerals and their products, special attention being devoted to securing industrial applications for newly discovered minerals or metallurgical products and to finding mineral materials required for new metallurgical products or inventions. Some of this information should be promptly and widely disseminated in summarised form to those interested in the industries, through the medium of the existing publications of the institutions directly concerned.

(3) The investigation of all questions and problems relating to the utilisation of the mineral or metallurgical resources of the Empire.

(4) The co-ordination and dissemination of information on mining laws, development of mineral areas, output, processes of extraction, plant, capital employed, markets, etc.

(5) A general review from time to time of the developed and undeveloped mineral resources and of the position of each mineral or metal, to ensure that the mineral wealth of the Empire is being exploited with due regard to Imperial interests.

(6) Generally, to advise the Imperial Government on all questions bearing on the mining and metallurgical industries. To perform this function efficiently, it is essential that complete information should be available, and also that the industries concerned should be consulted through their respective organisations.

We feel sure that the Advisory Council will fully appreciate the urgency of the question and the necessity for prompt action, so that the process of co-ordination may be inaugurated at once.

## THE BRITISH ASSOCIATION AT NEWCASTLE.

### SECTION I.

#### PHYSIOLOGY.

OPENING ADDRESS (ABRIDGED) BY PROF. A. R. CUSHNY, M.A., M.D., F.R.S., PRESIDENT OF THE SECTION.

*On the Analysis of Living Matter through its Reactions to Poisons.*

I WISH to-day to discuss an aspect of pharmacological investigation which has not been adequately recognised even by pharmacologists themselves, and which it is difficult to express in few words. In recent years great advances have been made in the chemical examination of the complex substances which make up the living organism, and still greater harvests are promised from these analytic methods in the future. But our progress so far shows that while general principles may be reached in this way, the chemistry of the living organ, like the rainbow's end, ever seems as distant as before. And, indeed, it is apparent that the chemistry of each cell, while possessing general resemblances, must differ in detail so long as the cell is alive. No chemistry dealing in grams, nor even microchemistry dealing in milligrams, will help us here. We must devise a technique dealing with millionths to advance towards the living organism. Here I like to think that our work in pharmacology may perhaps contribute its mite; perhaps the action of our drugs and poisons may be regarded as a sort of qualitative chemistry of living matter. For chemical investigation has very often started from the observation of some qualitative reaction, and not infrequently a good many properties of a new substance have been determined long before it has been possible

Digitized by Google

to isolate it completely and to carry out its analysis. For example, the substance known now as tryptophane was known to occur in certain substances and not in others long before Hopkins succeeded in presenting it in pure form. And in the same way it may be possible to determine the presence or absence of substances in living tissues, and even some of their properties, through their reaction to chemical reagents—that is, through the study of the pharmacology of these tissues. I do not claim that pharmacological investigation can at present do much more than the qualitative testing of the tyro in the chemical laboratory, but even a small advance in the chemistry of living matter is worthy of attention.

All forms of living matter to which they have free access are affected by certain poisons, and some of these have obvious chemical properties which suggest the method of their action; thus the effects of alkalies and acids and of protein precipitants scarcely need discussion. Others, such as quinine and prussic acid, which also affect most living tissues, have a more subtle action. Here it is believed that the common factor in living matter which is changed by these poisons is the ferments, and quinine and prussic acid may therefore be regarded as qualitative tests for the presence of some ferments, notably those of oxidation, and, in fact, have been used to determine whether a change is fermentative in character or not.

In other poisons the action on the central nervous system is the dominating feature, and among these the most interesting group is that of the simple bodies used as anæsthetics and hypnotics, such as ether, chloroform, and chloral. The important use of this group in practical medicine has perhaps obscured the fact that they act on other tissues besides the central nervous system, though we are reminded of it at too frequent intervals by accidents from anæsthesia. But while they possess this general action, that on the nervous tissues is elicited more readily. Not only the nerve-cell, but also the nerve-fibre react to these poisons, as has been shown by Waller and others. And even the terminations are more susceptible than the tissues in which they are embedded, according to the observations of Gros. The selective action on the nervous tissues of this group of substances has been ascribed by Overton and Meyer to the richness in lipoid substances in the neurons, which leads to the accumulation of these poisons in them, while cells containing a lower proportion of lipoid are less affected. In other words, Overton and Meyer regard these drugs as a means of measuring the proportion of lipoids in the living cell. This very interesting view has been the subject of much discussion in recent years, and, in spite of the support given it by several ingenious series of experiments by Meyer and his associates, no longer receives general acceptance. Too many exceptions to the rule have to be explained before the action of these bodies can be attributed wholly to their coefficients of partition between lipoids and water. At the same time, the evidence is sufficient to justify the statement that the property of leaving water for lipoid is an important factor in the action of the bodies, although other unknown properties are also involved in it. And whatever the mechanism of the characteristic action, these substances in certain concentrations may be regarded as tests for the presence of nervous structures, and have been employed for this purpose.

More interest has been displayed in recent years in the alkaloids which act on the extreme terminations of various groups of nerves. These are among the most specific reagents for certain forms of living matter which we possess. Thus, if an organ reacts to adrenaline, we can infer that it contains the substance characteristic of the terminations of sympathetic fibres with almost as great certainty as we infer the presence of a phenol group from the reaction with iron. And this sympathetic substance can be further analysed into two parts by means of ergotoxine, which reacts with the substance of the motor sympathetic ends, while leaving that of the inhibitory terminations unaffected. Similarly, the endings of the parasympathetic nerves are picked out with some exceptions by the groups represented by atropine and pilocarpine, and here again there must be some definite substance which can be detected by these reagents.

Further, some light has been thrown on, at any rate, one aspect of these nerve-end substances by the observation that they all react to only one optical isomer in each case. Thus the dextrorotatory forms are ineffective in both atropine and adrenaline, and this suggests strongly that the reacting body in the nerve-ends affected by these is itself optically active, though whether it bears the same sign as the alkaloid is unknown. This very definite differentiation between two optical isomers is not characteristic of all forms of living matter. For example, the heart muscle seems to react equally to both lævo- and dextro-camphor. The central nervous system contains substances which react somewhat differently to the isomers of camphor and also of atropine, but the contrast is not drawn so sharply as that in the peripheral nerve-ends.

The tyro in the chemical laboratory is not often fortunate enough to be able to determine his analysis with a single test. He finds, for example, that the addition of ammonium sulphide precipitates a considerable group of metals, which have then to be distinguished by a series of secondary reactions. The pharmacologist, as an explorer in the analysis of living matter, also finds that a single poison may affect a number of structures which appear to have no anatomical or physiological character in common. But as the chemist recognises that the group of metals which react in the same way to his reagent have other points of resemblance, so perhaps we are justified in considering that the effects of our poison on apparently different organs indicate the presence of some substance or of related substances in them. A great number of instances of this kind could be given, and in many of these the similarity in reaction extends over a number of poisons, which strengthens the view that the different organs involved have some common reacting substance.

One of the most interesting of these is the common reaction of the ends of the motor nerves in striated muscle and of the peripheral ganglia of the autonomic system. It has long been known that curare and its allies act in small quantities on the terminations of the motor nerves in ordinary muscle, while larger amounts paralyse conduction through the autonomic ganglia. These observations appear to leave no question that there is some substance or aggregate common to the nerve-ends in striated muscle and to the autonomic ganglia. Other analogies exist between the ganglia and the post-ganglionic terminations of the parasympathetic, as is shown by their reactions to the tetramethyl ammonium series; between the heart muscle and the cardiac inhibitory centre, as shown by digitalis and aconitine; between kidney-cell and ordinary muscle, as shown by caffeine and other purine bodies.

Many other examples might be cited in which organs which are apparently not related, either morphologically or in function, react to poisons in quantities which are indifferent to the tissues in general. And this reaction in common can only be interpreted to mean that there is some substance or group of related substances common to these organs. The reaction may differ in character; thus a drug which excites one organ to greater activity may depress another, but the fact that it has any effect whatever on these organs

Digitized by Google

in preference to the tissues in general indicates some special bond between them, some quality which is not shared by the unaffected parts of the body. I have, therefore, not differentiated between excitation and depression in discussing this relation. It seems probable that in this instance and in others the difference in the effect of these bodies in the tissues arises from differences in the behaviour of the molecule as a whole rather than in differences in the affinities of its special parts; that is, that the action of these poisons is due to their physical properties rather than to their chemical structure, although this, of course, is the final determining cause.

In the same way the common reaction of tissues, which I have so far ascribed to their possessing some substance in common, may arise from community of physical relationship, and I wish to avoid the implication borne by the word "substance," which I have used in the widest sense. The reaction of living tissue to chemical agents may arise from a specific arrangement in its molecule, but may equally be attributed to the arrangement of the molecules themselves. And the curious relationships in the reactions of different tissues may indicate, not any common chemical factor, but a common arrangement of the aggregate molecules. We are far from being able to decide with even a show of probability which of these alternatives is the correct one, and my object to-day has been to direct attention to these relationships rather than to attempt their elucidation.

## *UNIVERSITY AND EDUCATIONAL INTELLIGENCE.*

BIRMINGHAM.—The Vice-Chancellor, Lieut.-Col. Gilbert Barling, has been appointed consulting surgeon to the British Forces in France, and left Birmingham on November 1 to take up his duties. For some time past Col. Barling has acted as a consulting surgeon in the Southern Command. During his absence from Birmingham, which will extend over some months, his duties at the University will be discharged by Alderman F. C. Clayton, pro-Vice-Chancellor.

CAMBRIDGE.—The Vice-Chancellor has appointed Dr. R. T. Glazebrook to the office of reader on Sir Robert Rede's foundation for the ensuing year.

Mr. W. G. Palmer, who obtained first-class honours in both parts of the Natural Science Tripos, 1913–14, with distinction in chemistry, and was awarded the Hutchinson Studentship, has been elected to a fellowship at St. John's College.

Capt. E. Hindle, assistant to the Quick Professor of Biology, and formerly Beit Fellow for Medical Research, has been elected to the recently founded Charles Kingsley Lectureship in Natural Sciences at Magdalene College.

LONDON.—Lieut.-Col. H. R. Kenwood, professor of hygiene and public health in the University of London, will deliver a public lecture at University College, Gower Street, on "Hygiene: Some Lessons of the War," on Friday, November 17, at 5.30 p.m. The left without discretion in the matter. It was explained by Lord Milner that unless it were clearly laid down that the new scholarships should only be tenable by students within the Empire, much disappointment would be caused to applicants from other countries. Many will think this scarcely a sufficient reason for the trustees to wish to have their hands tied in the way proposed by the Bill.

---

WE learn from Wednesday's *Times* that Mr. H. Laming has just given 10,000*l.* to Queen's College, Oxford, to establish four scholarships of 100*l.* per annum, tenable for either three or four years, one to be offered each year. The scholars will, as a rule, be expected to take the Russian language for their honours degree. The idea is to provide a university course for candidates intending to follow a business career or to enter the consular service, and it is hoped that the scholarships may lead to a higher social and intellectual standard prevailing in those careers.

NOTICE has just been given of the next triennial prize at Guy's Hospital under the will of the late Sir Astley Cooper. The prize, the value of which is 300*l.*, will be awarded to the author of the best essay or treatise on "Gunshot Wounds of the Lungs and Pleura." The competition is open to all, with the exception of the staffs of Guy's and St. Thomas's Hospitals and their relatives. The competing essays, written in English, must be sent to Guy's Hospital on or before January 1, 1919. Further particulars of the competition may be obtained from Mr. C. H. Fagge, Guy's Hospital, S.E.

THE main thesis put forward by Mr. James Swinburne in a lecture on "Science and Industry," delivered at King's College, London, on November 1, Lord Moulton being in the chair, was that technology or applied science was outside the province of university teachers, who should concern themselves with imparting a knowledge of properties and principles, which they are eminently capable of doing, and leave the manufacturer to work out his own problems, of which academic people can have only second-hand knowledge. Mr. Swinburne understands, of course, that many great industrial advances have had their origin in what he called academic science, but what he wished particularly to emphasise was the difference between laboratory conditions and operations on an industrial scale brought to the point of commercial success. Purely scientific research must be free and independent, with the advancement of knowledge as its sole aim; but the manufacturer is only interested as a man of business in research which will give him financial advantage. Scientific knowledge is gained for the benefit of whomsoever may care to make use of it, whereas trade processes are kept secret or protected from adoption by industrial competitors by means of patents. The university should train workers in research methods, but the practical needs of industry can be understood only in the works themselves. Lord Moulton, in his remarks upon Mr. Swinburne's

Digitized by Google

to become managers of factories, while others leave factories to undertake teaching and scientific investigation. What is wanted is to bring science and industry in closer relationship, and that is not best accomplished by erecting a barrier of trade conditions between the laboratory and the factory.

THE Departmental Committee appointed by the President of the Board of Education to report upon the question of juvenile education in relation to employment after the war has considered it advisable, in view of the urgency of present circumstances, to issue an interim report recommending the Board to strengthen and extend, in co-operation with the Board of Trade, the system of juvenile employment bureaux and of local committees connected therewith. It emphasises the need also of after-care committees for juveniles from fourteen to seventeen years of age. The report directs attention to the fact that the exigencies of the war have caused large numbers of children to be drafted into employments that cannot be permanent and into other unsuitable employments, and that extensive dislocation, seriously affecting the conditions of juvenile employment, will surely arise after the war. It is stated that about 500,000 children enter into employment each year. To leave such children in the main without guidance is a serious dereliction of public duty, and requires that public bodies shall take up this necessary and urgent work. Having regard to the evidence placed before the committee as to school attendance, it might have been expected that it would have added to its recommendations in its interim report, in view of the serious evils which are induced thereby, the urgent need for the abolition of "half-time," so prevalent in Lancashire and Yorkshire, and of all exemptions which interfere with full-time attendance up to the age of fourteen. Two valuable handbooks, the like of which should be available in every area, dealing with the opportunities of employment of boys and girls in the cities of Edinburgh and Liverpool have been prepared, the former in 1908, the latter in January in the present year. Their purpose is to inform parents, and also to be a guide for teachers, of the conditions and possibilities of employment for their children. The oversight of children up to the age of seventeen at least is clearly within the province of the local education authorities, and it is to be hoped that the committee may further recommend in its final report the institution of measures which will ensure that all such children shall have facilities for continuing their education, both special and general, for at least six to eight hours per week within the usual hours of work.

AN interesting report of the proceedings of the Science Scholarships Committee of the Royal Commission for the Exhibition of 1851, dealing with the administration of the research scholarships since March, 1914, has just been issued, over the signature of Dr. Glazebrook, who has succeeded the late Sir Henry Roscoe as the chairman. The report deals with the science research scholars whose reports were examined in 1914-15, and includes scholars appointed so far back as 1909. Forty-five such scholars are reported upon, and it is gratifying to learn that out of this number the examiners were able to report that the work of thirty-nine of the scholars was satisfactory, and of seventeen of these eminently so as contributing results of high scientific value. It is interesting to observe that seven of the scholars took up industrial appointments on the conclusion of their period of research, whilst twenty-one entered upon university or scholastic appointments, and five entered the Government service to undertake specialised scientific work in the various research stations. Ten of the scholars entered directly into combatant service, either in the Army or Navy. Having regard to the vital importance of science in the development of industry, which the war has revealed with startling clearness, it would be very satisfactory to find a much larger number of research scholars entering into industry. The outbreak of the war rendered it impossible for scholars to proceed to German or other foreign laboratories, and other arrangements for their suitable employment in research were made. Many of the scholars elected to enter upon the prosecution of research bearing upon the requirements of the war. The committee had come to the conclusion to postpone all new appointments until after the war, but in deference to strong recommendations from the scientific advisers to the Government that it was desirable to maintain at the various university centres an adequate supply of qualified men to assist the Government in important investigations, it was decided not only to continue the scholarships, but also to offer six special war bursaries to organic chemists, the holders to undertake research under the direction of the Royal Society War Committee. The report indicates the manner in which the services of the scholars are being utilised in the preparation of explosives, drugs, dyes, etc., and in devising methods for improving war equipment or in combating disease.

## SOCIETIES AND ACADEMIES.

### LONDON.

**Challenger Society**, October 25.—Prof. E. W. MacBride in the chair.—G. H. **Fowler**: Physical conditions in the Kattegat. Seasonal variation was shown to depend on the sealing of the inner Baltic rivers by frost or their release by warmer weather.—C. T. **Regan**: Schmidt's second report on eel investigations. The importance of Schmidt's results in relation to the problem of the origin of species was pointed out.

**Mathematical Society**, November 2.—Annual general meeting.—Sir Joseph Larmor, retiring president, and afterwards Prof. H. M. Macdonald, newly elected president, in the chair.—Sir J. **Larmor**: (1) Presidential address. (2) The Fourier harmonic analysis: its practical scope, with optical illustration.—Prof. W. H. **Young**: Multiple integration by parts and the second theorem of the mean.—E. H. **Neville**: Moving axes and their uses in the differential geometry of Euclidean space.—J. **Hodgkinson**: Areas and conformal representation.

### PARIS.

**Academy of Sciences**, October 16.—M. Camille Jordan in the chair.—P. **Vuillemin**: Anomalies resulting from traumatism in plants.—R. **Soreau**: The graphical anamorphosis of a topographical surface.—C. **Zenghelis** and S. **Horsch**: The chemical action of sodium peroxide upon the oxides of carbon. Carbon dioxide forms sodium carbonate, with a marked rise in temperature, oxygen being evolved. Carbon monoxide forms sodium carbonate, the rise of temperature not being so great as with the dioxide, although the heat of combination is greater. It is suggested that a percarbonate is the primary product of the reaction between sodium peroxide and carbon dioxide.—L. **Guitteau**: The action of sulphur on baryta in presence of water. Evidence is put forward that an unstable barium pentasulphide, $BaS_5$, can exist in solution; this decomposes into barium tetrasulphide, $BaS_4$, barium thiosulphate, hydrogen sulphide, and sulphur.—P. **Gaubert**: The crystalline liquids obtained by evapora-

Digitized by Google

tion of a solution. Studies on liquid crystals from anisal-*p*-amidoazotoluene, ethyl anisalaminocinnamate, *p*-azoxyanisol; some cholesterol esters, and amyl cyanobenzalalamocinnamate.—F. **Grandjean**: The orientation of liquid anisotropes on crystals.—C. **Sauvageau**: The biological variations of *Saccorhiza bulbosa*.—Ch. **Dhéré** and G. **Vegezzi**: The pigmentary composition of hepatochlorophyll.—J. **Amar**: Sense education and prothesis apparatus. The results. The apparatus used in the re-education of the tactile sensibility in the stumps left after amputation has been described in earlier papers. Some of the results obtained are now described.

## DIARY OF SOCIETIES.

*THURSDAY*, NOVEMBER 9.

ROYAL SOCIETY, at 4.30.—Methods of Raising a Low Arterial Pressure: Prof. W. M. Bayliss.—Selective Permeability; the Absorption of Phenol and other Solutions by the Seeds of *Hordeum vulgare*: A. J. Brown and F. Tinker.—The Toxic Action of Dilute Pure Sodium Chloride Solutions on the Meningococcus: C. Shearer.—The *Rôle* of the Phagocyte in Cerebro-spinal Meningitis: C. Shearer and H. W. Crowe.—Investigation dealing with the Phenomena of "Clot" Formations. IV. The Diphasic Erosive Action of Salts on the Cholate Gel: S. B. Schryver and Mary Hewlett.—Some Photochemical Experiments with Pure Chlorophyll and their Bearing on Theories of Carbon Assimilation: Ingvar Joergensen and F. Kidd.

OPTICAL SOCIETY, at 8.—Some Notes on Glass Grinding and Polishing: J. W. French.

ROYAL GEOGRAPHICAL SOCIETY, at 5.—Natural Divisions of England: C. B. Fawcett.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Eighth Kelvin Lecture: Some Aspects of Lord Kelvin's Life and Work: Dr. A. Russell.

*FRIDAY*, NOVEMBER 10.

ROYAL ASTRONOMICAL SOCIETY, at 5.

MALACOLOGICAL SOCIETY, at 7.—Has Lymnæa an Auriculoid Ancestry? C. Hedley.—(1) *Anodonta cygnæa*, L., and *A. anatina*, L.; (2)

ROYAL MICROSCOPICAL SOCIETY, at 8.—The Microscopic Work of the Accademia dei Lincei: Dr. C. Singer.—A New Tank and Pond-weed Holder for use with Greenough Immersion Objectives: S. C. Akehurst.

ENTOMOLOGICAL SOCIETY, at 8.—The Factors which determine the Cocoon Colours of *Plusia moneta* and other Lepidoptera: Mrs. P. A. Merritt Hawkes.

ROYAL SOCIETY OF ARTS, at 4.30.—Opening Address: The Stability of Great Britain: Dr. Dugald Clerk.

*THURSDAY*, NOVEMBER 16.

ROYAL SOCIETY, at 4.30.

INSTITUTE OF MINING AND METALLURGY, at 5.30.

CHILD STUDY SOCIETY, at 6.—Experiments in Hand-writing in Schools: Speed Tests in Manuscript Writing: Dr. C. W. Kimmins.—The Artistic Aspect of Manuscript Writing: W. Scutt.—Manuscript Writing in a Central School: J. W. Samuel.—Manuscript Writing in a Boys' Elementary School: A. Sinclair.

LINNEAN SOCIETY, at 5.—(1) Pedanios Dioscorides of Anazarba; his Writings and his Commentators; (2) The New Cabinets for the Linnean Herbarium: The General Secretary.—A New Australian Genus of Hydrocharidaceæ: Dr. A. B. Rendle.—Some Collections of the Littoral Marine Fauna of the Cape Verde Islands, made by Cyril Crossland in the Summer of 1904: A. W. Waters.

*FRIDAY*, NOVEMBER 17.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—Report of the Hardness Tests Research Committee.

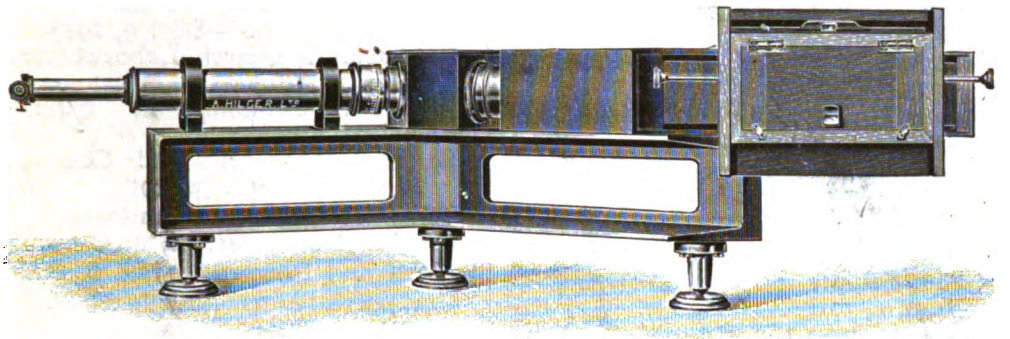
# HILGER QUARTZ SPECTROGRAPHS

**giving the whole spectrum from W.L. 8000 to W.L. 2100 in focus on a flat photographic plate.**



**A wave-length scale** extending over the above mentioned range can be supplied, so adapted that it can be photographed on the plate at the time of taking the photograph of the spectrum, the scale appearing in juxtaposition to the spectrum on development of the plate. The instruments are sent out completely adjusted and ready for photographs to be taken.

**Made in two sizes** { **Size A taking plates** $4\frac{1}{4}'' \times 3\frac{1}{4}''$. „ **C** (see above figure) **taking plates** $10'' \times 4''$.

***Complete description and specimen photographs post free on application to the Makers :***

## THE BRITISH OXYGEN COMPANY LTD.

**Works** for the production of **Oxygen** and other gases in **London** (Westminster, Greenwich and Stratford), **Birmingham, Cardiff, Wolverhampton, Manchester, Birkenhead, Sheffield, Newcastle-on-Tyne, Glasgow,** and **Sydney, N.S.W.**

**The Company** was formed in 1886 as Brin's Oxygen Company to develop means for the production of Oxygen on an industrial scale.

**The Company** is not only the acknowledged pioneer of the Oxygen industry, but possesses the largest organisation in the World for the production and distribution of that gas.

**The Company** also manufactures and supplies in cylinders, NITROGEN, HYDROGEN, CARBONIC ACID, and other gases.

**The Company** has developed an extensive engineering business, and has specialised in the design and manufacture of Plant for the production and separation of gases by liquefaction, electrolysis, and other methods.

**The Company** is the exclusive manufacturer in the United Kingdom of apparatus for metal cutting by Oxygen, and also manufactures well-known types of gas Regulators, Oxy-Acetylene and other blowpipes, and a large variety of apparatus for use with gas cylinders.

For illustrated price lists and full particulars application should be made to any of the Company's Works or to the Head Office, **Elverton Street, Westminster, S.W.**

## SECOND-HAND DEPARTMENT

**Microscopes, Telescopes, Spectroscopes, etc., by the best makers at moderate prices.**

*Instruments Bought, Taken in Exchange, or Sold on Commission.*

**JOHN BROWNING, 146 STRAND, LONDON.**

## BRITISH FOSSILS.

JAMES R. GREGORY & CO. have a large stock of the above, to which they are constantly adding new material. Specimens can be supplied in sets for Teaching purposes, and specimens for Demonstration and Museums can be had.

**JAMES R. GREGORY & CO., Mineralogists, &c.,**

**Some Features in**
**WATSON'S "VERSALIC" 1/12 in. OIL IMMERSION OBJECTIVE.**
It has no equal for Laboratory purposes, and is particularly designed for hot climates.

**Mechanical Points.**
The British Science Guild has recommended that Objectives should be sterilised before screwing home, to prevent growth of fungus, &c., in hot climates. This is done in the "Versalic" 1/12 in.
The B.S. Guild also recommended that the mounting should be of a colour to make the Lens easily distinguishable. The "Versalic" 1/12 in. is finished black.
In addition, the lenses are NOT set in their Cells with cement, which is apt to become unreliable, but all lenses are fixed with a metal bezel; they cannot therefore become displaced, the front lens cannot be "pushed in."

**Optical Points.**
Working distance of exceptional length—the maximum that can be given with maintenance of immersion oil contact. Unusually flat field. Corrected for use on stained objects.
Magnifying power is that of other 1/12 in. Lenses to which Laboratory workers are accustomed, viz. 1/10th in. It is a nominal 1/12 in. Definition is superb, and the Lens a pleasure to use.

The Objective is **British made.** It is designed for the Bacteriologist. It is especially recommended for hot climates. It will stand continuous rough working.

**PRICE £5. IMMEDIATE DELIVERY.**

WATSON'S MICROSCOPES are reliable and accurate. The demand exceeds the supply because their works are necessarily diverted to Optical Munitions. Inquiries are invited, and an approximate date for delivery will always be given.

# MACMILLAN & CO.'S NEW BOOKS.

## The Empire and the Future.

A Series of Imperial Studies Lectures delivered in the University of London, King's College. Crown 8vo. 2*s.* net.

CONTENTS:—Prefatory Note. By A. P. Newton, D.Litt.—Introduction. By A. D. Steel-Maitland, M.P.—The Universities and the War. By M. E. Sadler, C.B.—Empire and Democracy. By Sir Charles P. Lucas, K.C.B.—Imperial Administration. By H. A. L. Fisher, M.A.—The People and the Duties of Empire. By A. L. Smith, M.A.—Commonwealth and Empire. By P. H. Kerr, M.A.—The Duty of the Empire to the World. By G. R. Parkin, C.M.G.

## Discovery; or, The Spirit and Service of Science.

By **Professor R. A. GREGORY.** With 8 Plates. Crown 8vo. 5*s.* net.

*THE SCOTTISH CO-OPERATOR.*—"Professor R. A. Gregory has a reputation as the author of books on science well suited to the wants of students, and his latest is the most interesting of all, and will appeal to general readers as well as to systematic students, as they will find it more interesting than many of the novels which are put on the market."

VOLUME II. NOW READY.

## The Deposits of the Useful Minerals & Rocks; Their Origin, Form, and Content.

By **Dr. F. BEYSCHLAG, Prof. J. H. L. VOGT,** and **Dr. P. KRUSCH.** Translated by S. J. TRUSCOTT, Associate Royal School of Mines, London. Vol. II. LODES—METASOMATIC DEPOSITS—ORE-BEDS—GRAVEL DEPOSITS. With 176 Illustrations. 8vo. 20*s.* net. Previously published: Vol. I. Ore-Deposits in General—Magmatic Segregations—Contact Deposits—Tin Lodes—Quicksilver Lodes. With 291 Illustrations. 8vo. 18*s.* net.

*** These two volumes form the complete work on Ore-Deposits.

*THE MINING MAGAZINE.*—"Will doubtless rank for many years as a standard work on the subject. . . . English-speaking students of mining geology owe a heavy debt of gratitude to the translator for his services in rendering the subject-matter of such an important work readily accessible to them. He is to be congratulated on the successful completion of his difficult voluntary task."

COMPLETE IN 1 VOL. (Pts. I.–IV.) READY ON FRIDAY.

## A Class-Book of Chemistry.

By **G. C. DONINGTON,** M.A., late Senior Chemistry Master, City of London School, Author of "Practical Exercises in Chemistry." Illustrated. Crown 8vo. Part I. 1*s.* 6*d.* Parts I. and II. 2*s.* 6*d.* Parts II. and III. 2*s.* 6*d.* Parts I.–III. 3*s.* 6*d.* Part IV. METALS. 2*s.* Complete in 1 Vol. Pts. I.–IV. 5*s.*

## A Manual of Practical Physics.

By **H. E. HADLEY,** B.Sc., A.R.C.Sc., Principal of the School of Science, Kidderminster. Illustrated. Globe 8vo. 3*s.*

*THE SCHOOLMASTER.*—"The help to be derived from such a text-book is incalculable. To the lonely student it will come as a boon. Its exercises are workmanlike and searching, and its 265 pages are cheap at the price."

## A Text-Book of Practical Physics.

By **H. S. ALLEN,** M.A., D.Sc., Senior Lecturer in Physics, University of London, King's College, and **H. MOORE,** A.R.C.Sc., B.Sc., Lecturer in Physics, University of London, King's College. Extra crown 8vo. 8*s.* 6*d.* net. Also PART I. PROPERTIES OF MATTER. 3*s.* net. PARTS II., III., and IV. SOUND, LIGHT, AND HEAT. 3*s.* net. PARTS V. and VI. MAGNETISM AND ELECTRICITY. 3*s.* net.

*NATURE.*—"The book as a whole is a valuable addition to the list of text-books on practical physics, and the authors show an intimate acquaintance with the difficulties of both students and teachers which should make it very acceptable to both."

PART II. NOW READY.

## Practical Mathematics for Technical Students.

Part II. By **T. S. USHERWOOD,** B.Sc., Wh.Ex., A.M.I.Mech.E., and **C. J. A. TRIMBLE,** B.A. Crown 8vo. 7*s.* 6*d.*

*** Previously published: Part I. 3*s.* 6*d.*

*EDUCATION.*—"The examples are very numerous and well chosen, covering a wide field of engineering and physical problems, and there are some useful tables at the end. The book is decidedly of an advanced character, and the student who works systematically through the whole course ought to be able to tackle almost anything in the way of engineering problems."

FEBRUARY—JUNE PAPERS JUST PUBLISHED.

## Mathematical Papers for Admission into the Royal Military Academy and the Royal Military College, February–June, 1916.

Edited by **R. M. MILNE,** M.A., Assistant Master, Royal Naval College, Dartmouth, &c. Crown 8vo. Sewed. 1*s.* net.

## COUNTY BOROUGH OF HUDDERSFIELD TECHNICAL COLLEGE.

Principal: J. F. HUDSON, M.A., B.Sc.

DEPARTMENT OF COAL-TAR COLOUR CHEMISTRY.

"BRITISH DYES" RESEARCH SCHOLARSHIPS.

The Governors invite applications for two Scholarships of the value of £75 each and tenable for one year in the first instance.

The object of these Scholarships is to encourage and afford greater facilities for research upon problems in connection with the Coal-Tar Colour Industry in Great Britain. The Research is to be carried out in the Department of Coal-Tar Colour Chemistry of the Technical College, Huddersfield.

Full particulars may be obtained on application.

T. THORP, Secretary.

## SECONDARY SCHOOL (DUAL), CASTLEFORD, YORKS.

ASSISTANT MISTRESS required in January. Special subject—History. Salary £110 to £150, according to experience and qualification. Applications to be sent to the undersigned on or before November 24, 1916.

Mr. C. T. LIGHTLEY,
Clerk to the Governors.

77 Carlton Street,
Castleford.

## WOOLWICH POLYTECHNIC.

WANTED for January and for duration of war—

(1) TEACHER OF PHYSICS.
(2) TEACHER OF MATHEMATICS.

Applications are invited from men ineligible or discharged from military service, or from women.

ALEX. F. HOGG, Principal.

**ANATOMY ATTENDANT REQUIRED for Dissecting Room,** &c. Must be non-eligible for military service. Experience desirable, but not essential. Discharged sailor or soldier would be considered, if quick at learning. Apply (by letter only) to Box 838, c/o Messrs. R. F. WHITE & SON, General Advertising Agents, 33 Fleet Street, E.C.

**MASTER required to teach Nature Study and some English.** For particulars apply to HEADMASTER, Hulme Grammar School, Manchester.

**WANTED, the following quarter-sheets of the** 6-in. Ordnance Survey Map: Surrey XIII. N.E., and XIV., N.W., Edition 1897 (about). "E P.," Box 200, NATURE Office.

THURSDAY, NOVEMBER 16, 1916.

## NORTHERN COUNTIES LORE.

(1) *Highways and Byways in Galloway and Carrick.* By the Rev. C. H. Dick. Pp. xxix + 536. (London: Macmillan and Co., Ltd., 1916.) Price 6*s.* net.

(2) *Cleator and Cleator Moor: Past and Present.* By the Rev. Cæsar Caine. Pp. xviii + 475. (Kendal: Titus Wilson, 1916.) Price 21*s.* net.

(1) GALLOWAY, comprising the county of Wigtown and the Stewartry of Kirkcudbright, is probably less pervaded by tourists than any other attractive part of Scotland. Messrs. Macmillan have done well to commit to the Rev. C. H. Dick and Mr. Hugh Thomson the task of dealing with this district in their admirable "Highways and Byways" series, for these two gentlemen between them, one with his pen, the other with his pencil, have produced an ideal volume—not a guide-book in the ordinary sense so much as a *vade mecum* for the traveller. Mr. Dick, while not neglecting the highways, finds his chief delight in the byways and in those great tracts of moorland and mountain which constitute the southern upland of Scotland. Here he pursues his leisurely way, dropping off his bicycle at little wayside inns and lonely shepherds' cottages, at solitary pele-towers and immemorial kirkyards, wherever he may glean armfuls of legendary and historic lore. Galloway was the chief stronghold of the westland Whigs; memorials of the heroes and martyrs of the Covenant are as holy in his eyes as the sculptured crosses of the primitive Celtic church or the ruins of such noble fanes as Sweetheart and Dundrennan.

> Grey recumbent tombs of the dead in vacant places,
> Standing stones on the vacant wine-red moor,
> Hills of sheep, and the homes of silent vanished races,
> And winds austere and pure.

The killing, however, was not all done by Claverhouse and Lagg. The Covenanters did not shrink from shedding blood on occasions.

"Carsphairn abounds in hills of sheep and has its circle of standing stones, but is the only parish in the Glenkens where there is no martyr's grave. The village, however, has its story of the killing time. Pierson, the Episcopal minister, maintained a persecuting policy towards the Covenanters in the parish, and kept Lagg informed of those who absented themselves from church. The people were not cowed, but merely exasperated, and, led by James MacMichael, proposed to make some sort of treaty with the minister to secure peace in the parish. Pierson received a deputation in the manse, but on learning their errand was enraged, would listen to none of their remonstrances, barred the door, and drew out his pistol. Companions of the deputies, who had remained outside, hearing cries from within, broke down the door with MacMichael at their head. He, seeing the pistol outstretched and conceiving his friends to be in imminent danger, shot Pierson dead."

In treating of the scenery of Galloway Mr. Dick deals only with its external beauties and its association with legend and history. In a single volume so full of interesting matter it would be too much to expect detailed notice of fauna and flora. The geology of the district has been admirably explained in Sir Archibald Geikie's "Scenery of Scotland." There is, however, one feature which has long occupied the attention of geologists and deserves notice in any traveller's handbook. The prevailing formation in this region is Lower Silurian, the beds of which are tossed to a height of 2764 ft. in the Merrick, the loftiest summit in southern Scotland. Twelve miles S.S.W. of Merrick stands Cairnsmore-of-Fleet, 2331 ft., an intrusive mass of granite, altering the Silurian beds around it. On the very summit of Merrick lie many huge blocks of Cairnsmore granite, some of them as big as a small cottage. Ice-borne, no doubt, but how have they been carried to an elevation 400 ft. greater than that of the hill whence they came? The easiest explanation is that Cairnsmore has lost much of its original height by sub-aerial denudation.

We have but a single fault to find with Mr. Thomson's masterly pencil sketches, namely, that in his otherwise accurate drawing of the Peter Stone at Whithorn (p. 239) he has left out the Chi-Rho loop on the right of the upper limb of the cross. This is a serious omission, seeing that this feature, derived from the Emperor Constantine's *labarum*, occurs only on two other sculptured stones in Scotland, both in Galloway.

(2) Very different in scope and purpose from Mr. Dick's rambling notebook is the Rev. Cæsar Caine's "Cleator and Cleator Moor," which is a record, historical, industrial, geological, and biographical, of this famous ironfield. The earliest documentary evidence of iron-mining in West Cumberland is a deed of gift by William Earl of Albemarle, who died in 1179, of a mine at Egremont and a forge at Wynefell to the Abbey of Holm Cultram; but relics of the industry in prehistoric and Roman times have been found at Cleator and Furness. Mr. Caine discusses the various theories about the formation of hæmatite ore, such as aqueous deposition in solution, igneous injection, and chemical displacement or substitution, and agrees with J. D. Kendall in regarding the metasomatic replacement of limestone by ferrous carbonate as the prevailing cause, while less frequently hæmatite has probably been deposited in fissures by filtration.

The output from the Cleator mines shows so serious a falling off, namely, from 4,505,951 tons in the decade 1871–80 to 1,266,208 tons in the decade 1901–10, as to indicate the approaching close of the industry at no very distant date. Mr. Caine, however, looks forward to a day when "a man with large means and equal courage to carry out his ideas may bore through the coal measures which are known to overlie the car-

Digitized by Google

boniferous limestone in a large part of the neighbourhood of Cleator and find immense bodies of ore to reward him."

It is claimed for the Cleator Linen Thread Mill (now included in the great Thread Combine) that it is "the oldest flax-spinning mill in the country, and perhaps in the world." Winding thread on spools was first started here, the thread having previously been done up in hanks. It is strange, therefore, that Mr. Caine, in a dissertation upon place-names, should seek to connect that of a field close to the mill, Linethwaite, with the Anglo-Saxon "linde," a lime tree. It is plain Norse for "flax-field"—*lin-thveit*. A list of the flora and fauna of Cleator is given in an appendix, but it is valueless for any scientific purpose, inasmuch as none but English popular names are given. It does not carry one very far to be told that in this parish are found the linnet, the goose, the orchis, the gentian, etc., with no indication of species.

## A COMPOSITE AMERICAN TEXT-BOOK OF GEOLOGY.

*A Text-book of Geology*. By Prof. L. V. Pirsson and Prof. C. Schuchert. Part i., *Physical Geology*. By Prof. L. V. Pirsson. Pp. vii + 444. Price 10*s*. net. Part ii., *Historical Geology*. By Prof. C. Schuchert. Pp. vi + 405–1026. Price 12*s*. net. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1915.)

GEOLOGY, being such a many-sided science, is especially handicapped in regard to text-books. It is provided with a library of books dealing with its various subdivisions and aspects, but the provision of an up-to-date manual which deals with the whole range of the subject in about a thousand pages, and of the standard required by students in higher technical schools and by those taking geology as a secondary subject in universities, is a perennial difficulty. Specialisation in geology has gone so far that it is becoming impossible for any one author to deal with the whole science in the detail required in such a work. The new text-book of geology by Profs. Pirsson and Schuchert, with chapters by Profs. Barrell and Lull and Dr. Ulrich, show the effort to overcome this difficulty by joint authorship. That method has its own drawbacks, for it is very difficult thus to secure that unity of view and uniformity of standard which are indispensable in an educational text-book.

The first part of this work, by Prof. Pirsson, deals with physical geology. It is divided into two divisions, dynamical and structural, and in the course of 400 pages gives a most excellent summary of these subjects. Its illustrations are numerous and clear, and are all useful. Those illustrating the geological conditions of arid regions are especially good. His account of the igneous rocks is short and conservative, and British teachers may be grateful for the fact that he does not mention the American classification or adopt its terminology. A few relatively unimportant slips occur, such, for example, as the remark on p. 178 that the one boring in a coral atoll in the Pacific shows a thin cap of coral "on the volcanic rock which forms the main mass." The author attributes (p. 79) the fact that the Caspian is fresher than ordinary seas to the precipitation of its salt in Karabugas; but it would appear more probably due to the former dilution of the Caspian by the Volga. Prof. Pirsson introduces into geology the term "nonconformity" for those varieties of unconformity in which the dip of the formations is visibly different; for the other section of unconformities he accepts Grabau's term of disconformity. His description of pot-holes as a minor feature would appear to underrate their significance, for their formation is probably the main process by which mountain streams deepen their valleys in hard rock.

The chapter on the formation of mountains is one of the most interesting in the volume. In spite of some American opinions to the contrary, the author concludes that the crust is contracting in consequence of the lessened volume of the earth as a whole; and he is disposed to attribute the shrinkage, not to cooling, but to chemical changes in the internal material. He adopts also the steadily growing view that crustal movements occur with a rhythmic periodic progression; but the author will surprise many of his readers by his conclusion that the earth, "except locally or to a superficial depth, may not be hot, at least in any such sense that it could experience the notable contraction from loss of heat demanded for the origin of the folded ranges" (p. 366). The author refers to recent suggestions throwing doubt on the origin of the West American block mountains by faulting; but he concludes that the dominant processes in the formation of many, if not most, of these ranges are the faulting of the region and the tilting of the blocks. In his classification of mountains it is perhaps a pity that the author has not adopted the usual sequence of terms. He reverses the order of chain and system, and represents several mountain systems as forming a mountain chain; and he continues that a combination of mountain chains constitutes a cordillera. The term "cordillera" seems best restricted to a mountain system such as the Andes, composed of parallel chains.

Prof. Schuchert's part of the work, which is also published as a separate volume, consists of a most interesting series of essays. But it would appear of less use to British students as a college text-book than the first part. It is overweighted at the start by the long hypothetical pre-geological history of the earth. The arrangement of the material, and such illustrations as the portraits of geologists, are less suitable for the technical student than for the general reader; thus most students would probably have found it more convenient to have the descriptive palæontology all

together instead of distributed between the stratigraphical chapters.

Among the excellent features of this part is an explanation of the binomial nomenclature, which students are often expected to understand without any such help; but though the first edition of the "Systema Natura" was published in 1735, that is not accepted as the date of the establishment by Linnæus of the binomial system. The relegation of the technical names of the fossils illustrated in the text to an appendix is symptomatic of the present state of palæontological nomenclature; only general names are given in the legends of the figures. The use of popular names has the drawback that they vary so much locally, and English students are not likely to know what are meant by Sowbugs or Pillbugs (p. 605). The author accepts as undoubted the identification of some impressions in pre-Cambrian rocks of Brittany as radiolaria, though this conclusion is rejected by some who have examined the material. There is less evidence for the author's view that Eozoon is a calcareous alga than for its original reference to the Foraminifera, and it seems rather a "bull" to refer to some of these plants as fresh-water seaweeds.
